RE: Rio Grande Resource's Response to March 18, 2026 Comments from Mining Environmental Compliance Section of the New Mexico Environment Department for Closeout/Closure Plan, Revision 22-1 Permit No. CI002RE

Dear Mr. Ojekanmi,

Rio Grande Resources Corporation (RGR) is submitting the enclosed Update of the Closure/Closeout Plan, Revision 22-2, for the Mt. Taylor Mine (Permit No. CI002RE). This revision has been prepared in response to the comments provided by the Mining and Minerals Division (MMD) in its March 18, 2026 comment letter.

Also enclosed is a separate Response to Comments document that addresses each of MMD's comments and identifies the corresponding revisions made to the Closure/Closeout Plan.

RGR appreciates MMD's review of this submittal and looks forward to continuing to work with the Department throughout the review process. If you have any questions or require additional information, please contact me.

Respectfully Submitted,
**Rio Grande Resources Corporation**

|---|---|---|---|---|---|
| **Comment Letter, Mt. Taylor Mine, Update of Closure/Closeout Plan, Revision 22-1, Permit No. CI002RE (March 18, 2026)** | | | | | |
| 1 | Chapter 1 | Page 5, Para. 5 | **MMD "Comment 1" (March 18, 2026):**<br>Chapter 1, Page 5, Paragraph 5, claimed: The discharged water flowed northward from the San Lucas Canyon and disappeared approximately 22 miles from the point of discharge after comingling with the San Miguel Creek drainage system. What are RGR's plans to further investigate, characterize, and reclaim San Lucas Canyon? Can you provide information that describes the nature of investigation that will be completed in both San Lucas Canyon and San Miguel Creek; or a summary of existing investigations that will inform some remediation/reclamation of the Canyon? | The statement regarding treated mine water flowing approximately 22 miles downstream has been removed from the CCP. Upon review of the historical investigation reports, RGR did not identify documentation supporting this specific distance. The text has been revised to describe the historical downstream investigations that were completed without making an unsupported statement regarding the extent of historical surface water flow.<br>Additional discussion of the historical investigations completed downstream of Outfall 001 has been incorporated into Section 1.3.5 and 4.4.5, including the 2013 and 2014 investigations of soils, surface water, groundwater, sediment, and downstream impoundments. These investigations generally concluded that historical treated mine water discharges did not result in significant downstream environmental impacts requiring additional characterization at that time.<br>As part of the mine closure program, RGR is planning additional characterization of the San Lucas Canyon area immediately downstream of Outfall 001 to further evaluate the localized area of elevated gamma radiation identified during the 2020 radiological survey. AVM is currently preparing a work plan describing the proposed characterization activities. The results of the characterization will be used to determine whether remedial actions are warranted and to support completion of closure activities at Outfall 001.<br>Based on the historical investigations completed to date, additional investigation of San Miguel Creek is not currently planned. If the planned characterization identifies conditions that warrant further evaluation beyond the immediate Outfall 001 area, the scope of investigation will be expanded, as appropriate, in coordination with NMED. | |
| 2 | Chapter 3 | Page 47 | **MMD "Comment 2" (March 18, 2026):**<br>Chapter 3, Page 47: The shaft plugs as configured will need to include space for monitoring devices and sensors as may be required by NMED and OSE in the future. How does RGR intend to accommodate monitoring devices in the plug design? | Text updated in Section 4.3.1. With future design, the shaft plug design will identify a secondary sampling port. Both ports will be sized appropriately to accommodate the necessary monitoring devices and sensors required by NMED and OSE. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 3 | Chapter 4 | Page 26 to 27 | **MMD "Comment 3" (March 18, 2026):**<br>Chapter 4. Page 26 to 27: RGR intends to dispose of solid waste into either expanded disposal cells or offsite the facility. This implies that RGR classify waste generated from this closure operation into 2 broad groups, depending on the radiological properties. Also, RGR seems to be working under the assumption that there are only 2 broad classes of waste - based on radiological characterization. What are RGR's plans to manage more complex waste mixtures if there are more than 2 types of waste - e.g. organic/inorganic wastes, radiological and non-radiological wastes, complex mixtures of radio-impact soil-heavy metal, etc. Specifically, MMD is interested in cell design as related to radiologically contaminated soils combined with the diesel contaminated soils on-site. | RGR acknowledges that the CCP text may have implied a binary waste classification. In practice, RGR employs a multi-tiered waste classification protocol that considers radiological, chemical, and physical properties. The *Evaluation of Diesel Placement in Proposed Expanded Disposal Cell* (EA, 2026f) provides a comprehensive assessment specifically addressing the co-placement of diesel-impacted and radiologically elevated soils. Key findings are as follows:<br>1. Diesel-impacted soils at the site do not meet the definition of hazardous waste under RCRA — they are not listed wastes and do not exhibit hazardous characteristics (ignitability, corrosivity, reactivity, or toxicity per TCLP).<br>2. A spatial analysis confirms that elevated diesel concentrations (exceeding the NMED industrial SSL of 3,000 mg/kg TPH-DRO) do not spatially coincide with radiological hotspots (Ra-226 > 20 pCi/g). Therefore, the material does not constitute mixed radioactive and RCRA hazardous waste.<br>3. Where both contaminants co-occur (e.g., Mine Compound), diesel concentrations are well below the SSL (≤170 mg/kg).<br>4. The expanded disposal cell's design — clay liner, radon-attenuating cover, and long-term monitoring — is technically compatible with both waste streams.<br>If additional waste streams or more complex waste mixtures are identified during ongoing characterization, they will be evaluated using the same multi-parameter waste classification process. Waste management and disposal requirements will be determined based on the applicable regulatory criteria and the physical and chemical characteristics of the material.<br>The CCP has been revised to reflect this multi-tiered waste classification framework. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 4 | Chapter 4 | Page 27 | **MMD "Comment 4" (March 18, 2026):**<br>Chapter 4. Page 27. Can you confirm how long RGR intends to keep waste materials in the proposed staging areas? Please provide an overlay map of the proposed staging areas and how they will be protected from surface water or precipitation. | Waste materials stored within the three proposed staging areas will be managed on a temporary basis. The timing for relocation of staged waste materials to the expanded disposal cell will be determined as the sequencing of closure activities and disposal cell construction is finalized. Staged materials will be relocated to the expanded disposal cell as practical during implementation of the closure activities. The locations of the three NMED-approved staging areas and the surrounding stormwater drainage patterns are reflected in Figure 4-2 of the submittal. While the staging areas are open to direct precipitation, they are protected from surface water run-on and runoff through the following measures:<br>• **Siting:** The staging areas have been intentionally placed outside of concentrated surface water flows and within footprints previously approved by NMED in 2024 (NMED, 2024).<br>• **Runoff Controls:** Stormwater runoff from these areas is fully managed by the onsite stormwater engineering upgrades completed under the MMD-approved Permit No. CI002RE.<br>• **Permit Compliance:** These upgrades were specifically designed and constructed to support National Pollutant Discharge Elimination System (NPDES) compliance. They provide run-off controls and increased surface water retention capacity within the mine area. These controls are engineered to remain effective across all phases: active operating status, post-mining land use, and the long-term, post-closeout period. | |
| 5 | NA | NA | **MMD "Comment 5" (March 18, 2026): Mount Taylor Expanded Cell Design (June 06, 2025)**<br>Page 15: RGR uses the word "store and release, earthen cover system". Can RGR elaborate on the actual meaning and engineering implications of such cover system. Does this term imply an evapo-tranpirative (ET) cover? | The term "store and release" as used on Page 15 of the *Mt. Taylor Expanded Cell Design* (EA, June 2025) does indeed describe a cover system that functions on evapotranspiration (ET) principles, consistent with the terminology used in the New Mexico Copper Rule (20.6.7.33 NMAC). Specifically, a store-and-release cover is an earthen cover designed to temporarily store precipitation within the soil profile, then remove it through evapotranspiration, minimizing percolation into the underlying waste. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 6 | NA | NA | **MMD "Comment 6" (March 18, 2026): Mount Taylor Expanded Cell Design (June 06, 2025)**<br>Section 4.12: Can RGR elaborate on the functional implications of such ET cover system and how proposed cell extension will affect or complement the function of existing cover system. | The ET cover system for the proposed cell extension is designed to function in an integrated and complementary manner with the existing cover. Functionally, the store-and-release (ET) cover operates through three primary mechanisms:<br>1. **Surface interception and runoff**: The 12-inch rock mulch layer dissipates raindrop energy, reduces surface sealing, and promotes lateral runoff rather than infiltration.<br>2. **Soil moisture storage:** The 25-inch in-situ soil layer temporarily stores infiltrating water within its pore structure. Nominal AWHC is 0.10 $cm^3/cm^3$, yielding 2.50 inches of total storage capacity.<br>3. **Evapotranspiration removal**: While not required, the native vegetation, which is adapted to semi-arid conditions, draws moisture upward and releases it to the atmosphere via transpiration. The 12-inch clay radon barrier beneath the in-situ soil layer provides the final low-permeability boundary, preventing downward percolation (saturated hydraulic conductivity maintained per design).<br>The extended cover will tie into the existing cover along a designed transition zone, maintaining grade continuity, surface drainage patterns, and erosional stability. The existing cover's functions, which include radon attenuation, frost protection, erosion resistance, and infiltration control, are not diminished by the extension. Rather, the extension expands the protected footprint, reducing the area of unlined, impacted soils. The report revised by EA has included a more detailed functional description of the ET mechanism and the design interface with the existing cover. | |
| 7 | NA | NA | **MMD "Comment 7" (March 18, 2026): Mount Taylor Expanded Cell Design (June 06, 2025)**<br>Page 38, Fig 4.3: This figure claimed 1,093,840 volumes of storage will be created in the extension. Is this volume in cubic feet, cubic yard or m3. | The volume of 1,093,840 reported in Figure 4.3 of the *Mt. Taylor Expanded Cell Design* (EA, June 2025) is in cubic yards ($yd^3$). This value represents the total engineered storage capacity of the combined existing Waste Rock Pile (WRP) and the proposed disposal cell expansion.<br>The figure caption and associated text in the revised report has been updated to clarify the unit as cubic yards ($yd^3$) to eliminate any ambiguity. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 8 | NA | NA | **MMD "Comment 8" (March 18, 2026): Comments on Geotechnical Analysis of Borrow Sites**<br>RGR collected samples from three different test pits/locations as shown in Fig 1. Geotechnical analysis of samples was completed, but the data were not presented in spatial dimensions. If these data were projected spatially, can RGR confirm that there are sufficient fine graded soil materials within each of the 3 locations, such that each area has sufficient materials suitable as impermeable covers (clay) for the storage cells? | RGR acknowledges that the geotechnical data from the three borrow site test pits were presented in tabular form without explicit spatial projection. The three borrow locations (Borrow Areas A, B, and C) were selected based on field reconnaissance identifying zones of fine-grained soil within each area. Laboratory testing confirmed that samples from all three locations meet the geotechnical criteria for use as low-permeability cover material — specifically, Atterberg limits, particle size distribution, and compacted hydraulic conductivity consistent with the design requirement ($k \leq 1\times10^{-7}$ cm/s). The infiltration and stability analyses in the updated analysis used material properties derived from this borrow program (dry density ~1.51–1.59 g/cm³, porosity 0.35–0.38, etc.).<br>To directly address MMD's question: RGR confirms that based on field observations, test pit logs, and the spatial extent of each borrow area as shown in Figure 1 of the borrow site report, there is sufficient fine-grained material within each of the three locations to supply the clay cover material needed for the disposal cell construction.<br>A revised borrow site analysis section spatially maps the fine-grained soil zones within each borrow area and provides estimated volume yield calculations, confirming material adequacy. | |
| 9 | NA | NA | **MMD "Comment 9" (March 18, 2026): Comments on Geotechnical Analysis of Borrow Sites**<br>For areas deemed suitable as borrow sources of cover material, RGR should produce the radiological distribution of such areas to ensure that materials deemed suitable for cover soils based on geotechnical analysis do not have high radiological properties above the critical limit of 6.8 pCi/g. | Acknowledged. The report has been updated to include the radiological distribution for the areas identified as potential borrow sources. A discussion has also been added to the appropriate section describing the radiological characterization of the borrow areas and confirming that only materials meeting the applicable radiological criteria for use as cover material will be used in the final cover system. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 10 | NA | NA | **MMD "Comment 10" (March 18, 2026): Comments on Geotechnical Analysis of Borrow Sites**<br>RGR should include one or two paragraphs in this section, on how RGR intend to borrow soils that are suitable (from operation perspective, considering geology is not 100% clay), and exclude unsuitable cover materials from the same area. | RGR agrees with MMD's recommendation and has included a description of the operational protocol in the revised Geotechnical Analysis of Borrow Sites. The borrow site geology at Mt. Taylor is heterogeneous and includes fine grained silty clays, sandy silts, coarser gravels, and volcanic materials. Not all materials within the borrow footprint are suitable for use as low permeability cover. The following operational protocol will guide borrow site excavation and material selection:<br>1. **Pre excavation screening**: Before large scale excavation begins, each borrow area will be systematically test pitted at a spacing determined by the site geologist to map the lateral and vertical extent of fine grained and coarse-grained zones. GPS coordinates and elevations of suitable zones will be recorded.<br>2. **Field identification and segregation**: During active borrowing operations, a qualified soils technician or geologist will be present to perform visual classification and field testing, such Atterberg limits screening, on excavated materials. Materials that do not meet field classification criteria, such as excessive gravel content or a low plasticity index, will be segregated and stockpiled separately for use as noncritical fill or erosion armor.<br>3. **Quality assurance and quality control verification**: Representative samples of accepted material will be submitted for laboratory testing, including grain size analysis, Atterberg limits, compaction, and hydraulic conductivity, at a minimum frequency specified in the Construction Quality Assurance Plan.<br>4. **Stockpile management**: Accepted fine grained materials will be stockpiled on lined or protected areas and covered to prevent moisture loss or contamination before placement.<br>These procedures ensure that only geotechnically suitable materials are incorporated into the engineered cover system despite the natural variability of the borrow source geology. This description has been incorporated into the revised Geotechnical Analysis of Borrow Sites. | |

RE: Rio Grande Resource's Response to March 6, 2026 Comments from the Mining Environmental Compliance Section of the New Mexico Environment Department for Closeout/Closure Plan, Revision 22-1 Permit No. CI002RE

Dear Mr. Dimond,

Rio Grande Resources Corporation (RGR) is submitting the enclosed Update of the Closure/Closeout Plan, Revision 22-2, for the Mt. Taylor Mine (Permit No. CI002RE). This revision has been prepared in response to the comments provided by the Mining Environmental Compliance Section (MECS) of the New Mexico Environment Department (NMED) in its March 6, 2026 comment letter. Additionally, we have incorporated responses to the February 19, 2026, comments provided by the NMED Surface Water Quality Bureau (SWQB).

Also enclosed is a separate Response to Comments document that addresses each of the MECS and SWQB comments and identifies the corresponding revisions made to the Closure/Closeout Plan.

RGR appreciates MECS's review of this submittal and looks forward to continuing to work with the Department throughout the review process. If you have any questions or require additional information, please contact me.

Respectfully Submitted,
**Rio Grande Resources Corporation**

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| **Comment Letter, New Mexico Environment Department (NMED) Comments, Mt Taylor Uranium Mine, Updated Closure Closeout Plan, Mining Act Permit No. CI002RE** | | | | | |
| 1 | 1.3 | NA | **MECS "Comment 1" (March 6, 2026):**<br>2025 Closure/Closeout Plan, 1.3 Project History – The document could be improved with a figure showing pre-1971 disturbance that will not be addressed as part of the 2025 CCP. | RGR evaluated the availability of information to prepare a figure depicting pre-1971 disturbances. Although historical records indicate that exploratory drill pads and access roads existed prior to 1971, the locations of these historical disturbances were not documented and are not known with sufficient accuracy to develop a representative figure. Therefore, a figure has not been included. Section 1.3 has been revised to clarify the historical existence of these exploration disturbances and to reference the December 17, 1997, U.S. Forest Service recommendation regarding their reclamation. | |
| 2 | 1.3.5 | NA | **MECS "Comment 2" (March 6, 2026):**<br>2025 Closure/Closeout Plan, 1.3.5 Mine Water Treatment, Pumping, and Discharge– The Radiological Surveys of Discharge Pipeline report dated July 6, 2020, identifies an area of localized elevated gamma radiation at the discharge pipeline endpoint Outfall 001 that may be contaminated in excess of the 6.8 pCi/g site standard. Please account for any remaining soil impacts here to the volume of material requiring disposal. If all impacted soil has been removed, please provide the final gamma survey for the area of Outfall 001 to ensure reclamation is complete. | A comprehensive radiological evaluation of the Outfall 001 area has not yet been completed. In addition, the discharge pipeline removal work did not include excavation or removal of the radiologically impacted soil identified at Outfall 001. Consequently, the extent of any residual radiological contamination and the associated volume of material requiring management or disposal cannot currently be quantified.<br>The Outfall 001 area will be included in future closure characterization activities to determine the nature and extent of any remaining radiological impacts. Based on the results of that characterization, the volume of soil requiring excavation and disposal, if any, will be determined to support completion of reclamation and site closure. If any material is identified to be removed, it would be done when the disposal cell was ready to accept material. | |
| 3 | 3.3.4 | NA | **MECS "Comment 3" (March 6, 2026):**<br>2025 Closure/Closeout Plan, 3.3.4 Radiological levels for PMLU – This section references Nuclear Regulatory Commission (NRC) Regulatory Guide 1.86 criteria for radioactive contamination in habitable buildings. However, NRC guidance is not applicable in this case. Instead, MMD's 2016 joint guidance of 5 pCi/g Ra-226 above background (6.8 pCi/g at the site) should be applied. | The MMD 2016 joint guidance specifies the criteria for Ra-226 only for impacted soil cleanup. It does not specify any criteria for radiologic surface contamination limits for the release of equipment, material, and facilities. In the absence of MMD- or NMED-specific radiologic surface contamination release criteria for facilities, RGR has applied the conservative gross alpha surface contamination limit of 5,000 dpm/100 cm² contained in the MMD-approved March 2021 Site Radiation Protection Program Manual. The MMD requested that the gross alpha surface contamination limit for the PMLU at the Site would not exceed the dose limit of 100 mrem/yr.<br>In the 12/27/2021 Addendum to *Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands*, RGR calculated the radiologic release criteria consistent with the 25 mrem/yr radiological dose-based criterion for license termination and unrestricted use from Title 20, Chapter 3, Part 4, Subpart 426.B of the New Mexico Administrative Code (NMAC). The gross alpha surface contamination limit for the release of facility at the dose limit of 25 mrem/yr was calculated to be 2,364 dpm/100 cm². For a 100 mrem/yr dose limit, the gross alpha surface contamination would be 9,456 dpm/100 cm². This is because the relationship between surface contamination and dose is linear. However, RGR proposes the gross alpha surface contamination limit of 5,000 dpm/100 cm², as specified in NRC Regulatory Guide 1.86, which is well below the 9,456 dpm/100 cm² calculated based on the 100 mrem/yr dose. In addition, the gross alpha surface contamination limit of 5,000 dpm/100 cm² is specified in the MMD-approved March 2021 *Site Radiation Protection Program Manual*. | |

|---|---|---|---|---|---|
| 4 | 4.3.1 | NA | **MECS "Comment 4" (March 6, 2026):**<br>2025 Closure/Closeout Plan, 4.3.1 Shaft Plugging – NMED continues to have concerns regarding the long-term integrity of the shafts in relation to water quality. Procedures outlined in Appendix C.3 of the 2022 CCP continue to be referenced in the 2025 CCP. Appendix C.3 states "The remainder of the shaft, as well as connecting tunnels and raises, shall be backfilled with a cementitious slurry of soil, Portland cement, fly ash, and water". However, the volume of material to be added and the final backfill depth within the shaft have not been clearly specified. Water seepage has been documented at construction joints and horizontal cracks observed in the sub collar portion of the shaft, and the proposed concrete plugs will not extend to or seal all of these areas. NMED still remains concerned with the long-term stability of the shaft walls, due to potential concrete degradation and the potential lowering of the current water levels in the shafts due to future mining operations nearby. The added weight of the plugs on the shaft concrete is also concerning, given the documented degradation of the underlying shaft concrete. Additionally, NMED requests that a plan be developed for monitoring shaft water levels and water quality following backfilling of the shafts and plugging activities. The current Structural Design of Shaft Plugs diagrams in Appendix G indicate a steel pipe intended to function as a sampling well. Please provide additional details describing how a monitoring well will be incorporated in the final plug design. Also, the plan shall provide for additional new monitoring wells located in close proximity to the shafts, within each aquifer intersected by the shafts. This is required for monitoring groundwater quality and protection the surrounding aquifers. | The shaft plugging design consists of constructing a structural plug at the subcollar level. Following construction of the structural plug, controlled low-strength material (CLSM) backfill will be placed only within the shaft interval above the structural plug, as shown on the shaft closure drawings. The final plug elevations, backfill limits, and associated backfill material volumes will be refined during final design and documented in future design submittals. Refer to Appendix G, Drawings C/100 and C/200, and the associated shaft closure design details for the conceptual plug and backfill configuration.<br>To address the observed near surface sub-collar seepage, field evaluations are currently being conducted under the 2025 approved *Site Investigation Plan* (EA, 2025a); it is anticipated that a targeted plan to seal off this seepage will be developed based on these findings.<br>Furthermore, to address concerns regarding plug stability and the added weight on the legacy shaft concrete, the final shaft closure design will incorporate measures to transfer the structural loads from the shaft plug into competent host rock, such as engineered horizontal keyways, or another engineered approach determined during final design. The final design will support the plug independently of the existing shaft walls and minimize reliance on the long-term integrity of the shaft concrete or future regional water-level fluctuations. The final shaft closure design will be submitted to NMED for review and approval prior to construction.<br>The *Post-Closure Monitoring Plan* (PCMP) will be updated to address long-term monitoring of groundwater levels and water quality following shaft plugging activities. The updated monitoring program will include proposed monitoring wells in the vicinity of the shafts, as appropriate, and will be submitted to NMED for review and approval prior to implementation.<br>Two redundant, structurally isolated steel monitoring ports will be incorporated into each individual shaft plug to provide redundant groundwater sampling access. The final monitoring port design will be included in the final shaft plugging design submitted for agency review. | |
| 5 | 4.4.2 | NA | **MECS "Comment 5" (March 6, 2026):**<br>2025 Closure/Closeout Plan, 4.4.2 Disposal Cell and Expansion - In Permit Condition 32 of DP-61 dated October 14, 2015, NMED requires RGR to document the construction quality assurance (CQA) of all clay liners and caps of the disposal cell. Please add the following language from Permit Condition 32 to the updated 2025 CCP. "CQC and CQA plans shall be submitted to NMED for approval a minimum of 30 days prior to beginning of construction of the clay liner. Within 60 days following completion of construction of the clay liner, a CQA report and as-built plans shall be submitted to NMED." | This language has been added to Section 4.4.2 of the CCP and the *Expanded Disposal Cell Design* report (Appendix K). | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 6 | NA | Page T-30<br>Table 4-3 | **MECS "Comment 6" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Former Lagoon, Table 4-3, Page T-30 – The former sewage lagoon was mentioned as a possible source of elevated nitrate in monitoring well WP-5 in the Stage 1 Abatement Plan in 2005. In the 2021 Site Investigation Plan (2021 SIP), RGR had originally proposed to excavate the sediments and waste rock in the former sewage lagoon and surrounding area to remove any uranium and nitrate source material. Currently, RGR estimates that approximately 10,680 cubic yards of sediment and waste rock are present in the former lagoon. This volume has been added to Table 4-3 of the updated 2025 CCP and is listed as Sediment and Waste Rock in the Former Lagoon. A note in Table 4-3 states, "Volumes associated with the former lagoon are included per NMED request. It is not likely that the material will be excavated and transferred to the disposal cell." Please clarify whether excavation of the former lagoon material is a planned activity. If so, describe how the work would be conducted and coordinated with disposal cell expansion activities. In addition, please propose a plan to for additional source characterization and removal delineation. | The sediment and waste rock within the former lagoon have been included in the estimated disposal cell volume in response to NMED's request. However, excavation of this material is not currently identified as a planned closure activity.<br>The need to excavate the former lagoon material will be evaluated as additional information becomes available. One consideration is whether the material could adversely affect the final disposal cell design or long-term performance, since the former lagoon is located beneath the proposed disposal cell footprint. A second consideration is whether future Site Investigation Plan (SIP) investigations and subsequent groundwater abatement activities indicate that the former lagoon sediments and waste rock represent a continuing source of groundwater impacts that cannot be addressed through other remedial measures. If future investigations determine that removal of the material is necessary, a source characterization and removal delineation will be completed to define the extent of material requiring excavation. If needed, the excavation approach and coordination with disposal cell construction activities will be developed as part of the final closure design and submitted to NMED for review and approval. | |
| 7 | NA | NA | **MECS "Comment 7" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Lack of Abatement Strategy - Current abatement activities (i.e., shallow extraction wells, etc.) have not fulfilled abatement per NMAC 20.6.2.4103. While the upcoming site investigation activities related to the approved 2025 Revised Site Investigation Plan will help better define the extent of the shallow groundwater plume, they do not address all components necessary of site-wide abatement. Groundwater monitoring alone is not abatement nor a remedial strategy. NMED will work with RGR to continue abatement activities and will recommend a modification of the approved CCP when consensus is reached by all parties. | RGR acknowledges NMED's comment regarding the distinction between ongoing site investigations and groundwater monitoring activities and the development of a comprehensive, site-wide abatement strategy under NMAC 20.6.2.4103.<br>RGR agrees that groundwater monitoring and operation of the current shallow extraction wells alone do not constitute a final remedial solution. The primary objective of the approved 2025 *Revised Site Investigation Plan* (EA, 2025a) is to better delineate the extent and nature of groundwater and to collect the information necessary to evaluate and develop effective long-term abatement alternatives. This information is needed before an appropriate site-wide abatement strategy can be developed.<br>RGR appreciates NMED's willingness to continue working collaboratively on the development of a long-term abatement strategy. Following completion of the site investigation and evaluation of the results, RGR will work with NMED to develop an appropriate abatement approach and, as necessary, modify the CCP to incorporate the selected remedial strategy. | |
| 8 | NA | Page T-30<br>Table 4-3 | **MECS "Comment 8" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Disposal Cell Capacity, Table 4-3, Page T-30 - The estimated total volume of impacted soils is now listed as 418,167 cy in Table 4-3. NMED notes this volume does not include work currently underway to determine soil volumes from the South Controlled Area, nor does it include other potential future studies. If this work will be completed prior to the finalization of a cost estimate, it needs to be included. If it is not completed, NMED recommends a conservative estimate be included based on current knowledge with 20% contingency added. RGR can update this estimated volume after the completion of work in a future update to the CCP.<br>In the June 30, 2025 response, RGR provided updated soil volumes included in Attachment A – Summary of Material Scheduled for the Disposal Cell. Attachment A lists 942,450 cy as the "Disposal Cell Capacity at 25 Acres". The updated 2025 CCP states that the expanded disposal cell will be up to 13.5 acres, bringing the combined area of the existing Waste Rock | The disposal cell capacity listed in Table 4-4 represents the total capacity of the combined existing Waste Rock Pile (WRP) and the expanded disposal cell. As part of the October 15, 2025 CCP submittal, the disposal cell design was revised, increasing the total estimated disposal cell capacity from 942,450 cubic yards to 1,093,840 cubic yards.<br>Table 4-4 has been updated to include the estimated disposal volumes for the South Controlled Area based on the current characterization results. RGR acknowledges that additional characterization activities may identify other materials requiring disposal. As additional information becomes available, the estimated disposal volumes and closure cost estimate will be updated, as appropriate. If characterization activities are not completed prior to finalization of the closure cost estimate, conservative estimates, including appropriate contingency, will be incorporated, as appropriate. | |

|---|---|---|---|---|---|
| 9 | NA | Figure 4-1 | **MECS "Comment 9" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Figure 4-1 - Figure 4-1 of the updated 2025 CCP appears to indicate that portions of the existing WRP/disposal cell would be regraded or that the pre-existing slope would be modified. Please clarify if the proposed design changes will be incorporated to ensure protections for minimal disturbance of existing reclamation. Please clarify if the new cover design result in modification of the entire existing disposal cell facility or only be applicable to the new 13.5 acre expanded disposal cell. If the new design is not over the existing facility, please explain the transition area between the two designs. Please explain how groundwater monitoring well MW-11A and the newly proposed extraction well RW-11AR will be accommodated in the proposed design. | **(1) Existing WRP/Disposal Cell Disturbance:** The proposed design changes are limited exclusively to the 12-acre expanded disposal cell area. The existing WRP/disposal cell and its established reclamation will not be disturbed or regraded. The existing cover system will remain in place and is not subject to modification under the current design. Figure 4-1 has been updated for clarity.<br>**(2) Transition Zone:** A graded transition zone will be designed at the interface between the existing disposal cell and the expanded cell. This zone will taper the cover layers to match existing grades and avoid abrupt geometric discontinuities. Specific transition geometry, including slope and layer pinchout details, will be provided in the final construction drawings to be submitted for approval at a later date.<br>**(3) Wells MW-11A and RW-11AR:** The final grading plan will include adequate setbacks and access routes for both wells to ensure continued operability throughout and after construction. | |
| 10 | Appendix H | Table 2 of PCMP lists | **MECS "Comment 10" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Appendix H - Table 2 of the PCMP lists the proposed Point of Compliance (POC) wells, including MW-1M, MW-5, WP-5, MW-11A, DW-3, DW-10, DW-11, DW-14, and DW-19. NMED agrees with the use of wells MW-1M, MW-5, WP-5, and MW-11A for long-term monitoring of the Alluvial/Menefee aquifer. NMED also requests that existing monitoring well MW-4 and the planned MW-13 (upcoming Site Investigation activities), be included as POC wells for the Alluvial/Menefee aquifer to address downgradient data gaps associated with the expanded disposal cell. Based on a September 25, 2025 technical memorandum from the Office of the State Engineer (OSE), DW-13 has been determined to have a low probability of inter-aquifer exchange, and NMED therefore concurs that it may be suitable for long-term groundwater monitoring of the Westwater aquifer. However, wells DW-3, DW-10, DW-11, and DW-19 are not suitable long-term groundwater monitoring wells. All four wells have been classified by OSE as having either possible inter-aquifer exchange or probable inter-aquifer exchange. In addition, wells DW-3, DW-10, and DW-11 currently have confirmed hydrocarbon releases, with several contaminants of concern above NMWQCC standards. NMED therefore requests installation of four new, dedicated wells designed specifically for long-term monitoring of the Point Lookout and Tres Hermanos aquifers, as these legacy dewatering wells are not in a condition to provide accurate long-term groundwater data. NMED will work with RGR on the location of and timing for the new monitoring wells, however cost for installation and long-term care need to be included in an updated cost estimate. A placeholder for these wells should be added to the PCMP for inclusion in the updated CCP. | The *Post-Closure Monitoring Plan* (PCMP) was updated as part of this CCP submittal to address NMED's comments regarding the proposed Point of Compliance (POC) monitoring network.<br>Regarding the Westwater aquifer, RGR notes a discrepancy in the agency's reference to well DW-13. A review of the September 25, 2025 Office of the State Engineer (OSE) documentation indicates that DW-14 (B-516-POD40) was identified as the Westwater well with a low probability of inter-aquifer exchange. Conversely, the OSE directive explicitly lists DW-13 among the wells requiring a plan to investigate the potential for inter-aquifer exchange, or a repair/plugging plan. Based on this OSE clearance, RGR assumes NMED's concurrence for long-term groundwater monitoring is intended for DW-14 rather than DW-13, and the PCMP has been updated to reflect DW-14 as the appropriate POC well.<br>RGR acknowledges NMED's concerns regarding the long-term suitability of dewatering wells DW-3, DW-10, DW-11, and DW-19 for post-closure groundwater monitoring. The updated PCMP includes placeholders for proposed new dedicated monitoring wells for the Point Lookout and Tres Hermanos aquifers. The final number, locations, and construction details of these wells will be developed in coordination with NMED.<br>The updated CCP closure cost estimate will include placeholder costs for the installation, long-term monitoring, maintenance, and eventual abandonment of the proposed monitoring wells, as appropriate. | |

|---|---|---|---|---|---|
| 11 | Past Attachments/Addenda | NA | **MECS "Comment 11" (March 6, 2026):**<br>2025 Closure/Closeout Plan, Past Attachments/Addenda - The CCP should be revised into a single, consolidated document. For example, Attachment A—Summary of Material Scheduled for the Disposal Cell—from the June 30, 2025 RGR response to CCP comments was not included in the updated 2025 CCP, while the Post Closure Monitoring Plan received on June 30, 2025, was included as Appendix H. Please update Attachment A as needed and include it, along with all other separate necessary addenda, as attachments or appendices to an updated CCP. | The Summary of Material Scheduled for the Disposal Cell has been updated and incorporated into Table 4-4 of the updated CCP. RGR also reviewed prior CCP attachments, appendices, and addenda and incorporated relevant information into the updated CCP, as appropriate, to provide a consolidated document. To the best of RGR's knowledge, all necessary supporting materials have been incorporated into the updated CCP. | |
| 12 | 4.2 | NA | **MECS "Comment 12" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.2 Description of Cover - Please provide a detailed explanation of the purpose of the coarse sand capillary break layer in the updated disposal cell cover design. Also, please provide some examples of where this layer has been effectively used in cover designs. NMED has not approved of a layer of this nature in a cover design, therefore is not approving of it without support and evaluation for an alternative design. | Engineering Analytics (EA) has completed a detailed critical review of the capillary break layer requirement. Based on this analysis, EA recommends eliminating the coarse sand capillary break layer from the cover design. The revised optimized 3-layer cover system — 12-inch rock mulch / 28-inch in-situ soil / 12-inch compacted clay — has been confirmed by radon diffusion analysis to yield a surface flux of approximately 13.99 $pCi/m^2 \cdot s$, well below the 20 $pCi/m^2 \cdot s$ regulatory limit. The capillary break layer is accordingly not included in the revised design. | |
| 13 | 4.6.3.1 | NA | **MECS "Comment 13" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.6.3.1 Climate Data Used for Analysis - The model results of the infiltration analysis indicate that the mean annual percolation value through the cover system is 0.45 inches/year or 7.4% of the mean annual precipitation value. This would indicate that the mean annual precipitation determined for the mine site would be 6.1 inches per year. Monthly climatological summaries for the Mt. Taylor mine site from 2018 – 2025 reported in DP-61 quarterly monitoring reports show a mean annual precipitation of about 10 inches per year. Please explain the discrepancy between those values and the mean annual precipitation values presented in the CCP. Additionally, please explain why Rice Park, NM, is used as the primary source of historical weather data. Rice Park is located approximately 30 miles to the west of Mt. Taylor mine and in a different mountain range. | EA acknowledges NMED's comment and provides the following clarification.<br>**(1) Precipitation Values Used in the Model:** We acknowledge the discrepancy in the previous draft, which contained a calculation error. The revised *Expanded Disposal Cell Design* report has been updated to explicitly use the continuous on-site meteorological data from the San Mateo station (2018–2025) as the primary dataset for the infiltration analysis. The documented on-site mean annual precipitation (MAP) is 10.01 in/yr. Using this site-specific precipitation input, the revised SEEP/W transient numerical model yields a long-term mean annual percolation rate of 0.40 in/yr through the cover system. This corrected percolation value accurately represents 4.0% of the MAP<br>**(2) Rice Park Weather Station:** We agree that on-site data should serve as the primary climatic reference. As noted above, the revised Expanded Disposal Cell Design now utilizes the on-site San Mateo data (2018–2025) as the primary dataset for the water balance, infiltration, and Copper Rule analyses. Regarding Rice Park, we would like to clarify that the SNOTEL station is located approximately 20 miles northeast of the mine, not 30 miles west. While the on-site data drives the infiltration model, Rice Park was retained solely as a supplemental dataset to evaluate long-term winter hydrology (e.g., snow water equivalent and freeze-thaw behavior). Because the on-site station record is relatively short, the Rice Park data is necessary to conservatively project the Air Freezing Index (AFI) for the 200-year return period frost penetration analysis. To validate this approach, a statistical comparison was performed; the results demonstrated no significant departures ($p > 0.05$) between the on-site San Mateo record and the long-term regional datasets, confirming that the site data falls within normal regional variability. Additional discussion clarifying the specific applications of these datasets has been added to Section 2.6 of the design report. | |

|---|---|---|---|---|---|
| 14 | 4.6.4 | NA | **MECS "Comment 14" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.6.4 Results of Infiltration Analysis - The infiltration analysis in the Expanded Disposal Cell Design Report does not provide the modeled available water holding capacity for the cover. NMAC 20.6.7.33.F.(2) states that soil cover systems shall be designed to limit net-percolation by having the capacity to store within the fine fraction at least 95 percent of the long-term average winter (December, January and February) precipitation or at least 35% of the long-term average summer (June, July and August) precipitation, whichever is greater. Please provide the available water holding capacity of each of the cover layers above the waste material. | EA has revised and finalized the Available Water Holding Capacity (AWHC) analysis for the cover system. This complete layer-by-layer breakdown and Copper Rule compliance evaluation has been added to Section 4.6.5 of the *Expanded Disposal Cell Design* report. The analysis summary is provided below.<br>**Material Properties and Available Water Holding Capacity (AWHC):** Based on the soil-water characteristic curves (SWCCs) derived from the Mt. Taylor borrow source characterization program (Appendix B), the AWHC for the 28-inch on-site soil cover layer (classified as CL-ML) is **0.10 in/in**. This is determined from a volumetric water content at field capacity ($\theta_{fc}$) of 0.20 minus the volumetric water content at the wilting point ($\theta_{wp}$) of 0.10.<br>• **Rock Mulch Layer (12 inches):** Not credited with fine-fraction water storage.<br>• **On-Site Soil Cover (28 inches):** Provides the primary fine-fraction moisture storage. Total storage capacity = 28 inches × 0.10 in/in = **2.80 inches**.<br>• **Compacted Clay Barrier (12 inches):** Storage is conservatively excluded from this calculation, as this layer serves as the primary low-permeability radon and infiltration barrier.<br>**Copper Rule Compliance:**<br>Using the reconciled on-site precipitation record (2018–2025 San Mateo station) presented in Table 4-4 of the design report, the governing storage requirement under NMAC 20.6.7.33.F.(2) is the greater of:<br>1. Long-term average winter (December, January, February) precipitation × 95%<br>2. Long-term average summer (June, July, August) precipitation × 35%<br>Based on the site data:<br>• December, January, February Precipitation = 0.94 inches (95% = **0.89 inches**)<br>• June July August Precipitation = 4.70 inches (35% = **1.65 inches**)<br>The strict regulatory requirement based on the 3-month seasonal definitions is **1.65 inches**. The 2.80 inches of storage provided by the 28-inch on-site soil layer easily exceeds this requirement.<br>Furthermore, as documented in Section 4.6.5 of the *Expanded Disposal Cell Design*, EA evaluated the cover against a more conservative 6-month seasonal criteria (Winter: Oct–Mar; Summer: Apr–Sep). Under this highly conservative evaluation, the required storage capacity was 2.73 inches. The storage capacity provided of 2.80 inches exceeds even this more rigorous standard, confirming full compliance with the Copper Rule store-and-release performance criteria. | |

|---|---|---|---|---|---|
| 15 | 4.11.2.3 | NA | **MECS "Comment 15" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.11.2.3 Rock Mulch Borrow Sources - Please confirm the D50 rock size of the AASHTO No. 1 gravel proposed for the rock mulch cover and explain why this size is appropriate | The AASHTO No. 1 gravel specified for the rock mulch admixture has a nominal $D_{50}$ (median rock size) of approximately 2.2 inches. The complete gradation and supporting engineering analyses have been incorporated into Section 4.9 and Appendix I of the *Expanded Disposal Cell Design* report.<br>This specific size range is appropriate for the Mt. Taylor disposal cell cover for the following reasons:<br>**1. Water Erosion Resistance (PMP Design Storm):** The rock size was evaluated using the Abt-Johnson method, as recommended in NUREG-1623 and NUREG/CR-4620. For the engineered 5H:1V (20%) cover slopes, the required $D_{50}$ to resist the Probable Maximum Precipitation (PMP) event increases with slope length. At the maximum designed unsupported slope run of 250 feet, the required $D_{50}$ is 2.04 inches. The provided AASHTO No. 1 gravel $D_{50}$ of 2.20 inches exceeds this requirement, ensuring individual particles resist displacement under maximum expected surface flow conditions.<br>**2. Gully Formation and Armoring:** Gully formation was evaluated using the Shield's incipient motion equation and Pemberton and Lara (1984) scour-depth calculations. The analysis confirms that the critical particle size to resist movement is 4.15 inches; the larger fraction of the AASHTO No. 1 gravel provides these coarser particles. This ensures that a protective armor layer will naturally develop within the 12-inch rock mulch admixture depth (calculated scour depth of 10.3 inches) before any scour can reach the underlying moisture-storage soil layer.<br>**3. Wind Erosion Protection:** The admixture blend (30% AASHTO No. 1 gravel and 70% on-site soil) creates a durable surface. As wind and minor water action winnow away surficial fines, the 2.2-inch gravel forms a self-reinforcing desert pavement. Wind Erosion Prediction System (WEPS) modeling for comparable covers in the Grants Mineral Belt demonstrates that this coarse fraction keeps annual soil loss well below the EPA benchmark of 2 tons per acre per year.<br>**4. Regional Precedent and Vegetation Support:** This 30% gravel admixture approach is consistent with successful, analogous uranium mill tailings closures in the Grants Mineral Belt. The AASHTO No. 1 gravel size is large enough to provide the necessary physical armoring, while the 70% soil matrix retains sufficient fines to successfully support the shallow-rooted native vegetation required for the store-and-release cover's evapotranspiration functions. | |

|---|---|---|---|---|---|
| 16 | 4.14 | NA | **MECS "Comment 16" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.14 Material Placement - The Expanded Disposal Cell Design Report states that petroleum-contaminated soil may be land farmed prior to placement, whereas the updated 2025 CCP does not mention land farming and instead states that all soils exceeding diesel and uranium cleanup standards will be excavated and placed in the disposal cell. Table 4-3 of the CCP estimates up to 24,600 cy of diesel-contaminated soil, with volumes subject to increase as the investigation continues. Please confirm whether land farming of diesel-contaminated soil is being proposed. If so, explain how land farming of diesel contaminated soil containing uranium and radium above screening levels would be managed to prevent additional environmental hazards, including but not limited to wind-blown, surface water, and groundwater impacts. Also describe any alternative method other than land farming if the soil contains free liquids and fails a paint filter liquids test. NMED continues to approve placement of diesel-contaminated soil in the expanded disposal cell provided it passes the paint filter liquids test. | Land farming of diesel-contaminated soils is not proposed as a primary disposal method in the current design. The reference to land farming in the previous *Expanded Disposal Cell Design* report reflected an earlier contingency that has since been eliminated. The revised *Expanded Disposal Cell Design* has been updated to remove this language and avoid confusion.<br>**Approved Approach:** All excavated soils exceeding diesel and/or uranium/radium cleanup screening levels will be managed in accordance with the current *Closeout/Closure Plan* and placed in the expanded disposal cell, provided they pass the paint filter liquids test in accordance with 40 CFR 261, Appendix II. This approach is consistent with NMED's approval.<br>**Free Liquids Management:** If excavated soils fail the paint filter liquids test, they will not be placed in the disposal cell until they have been managed to eliminate free liquids and subsequently pass the paint filter liquids test. No land farming of these materials is proposed. | |
| 17 | 4.14 | NA | **MECS "Comment 17" (March 6, 2026):**<br>Expanded Disposal Cell Design, 4.14 Material Placement - Please confirm the proposed compaction of all cover design layers. It appears that a minimum of 90 percent of the maximum dry density is proposed for the various cover layers, but it is not clearly stated in the Expanded Disposal Cell Design Report. | EA confirms that a minimum compaction standard of 90 percent of the maximum dry density (per Standard Proctor) is specified for the compacted earthen cover layers, specifically the on-site soil cover and the underlying clay radon barrier. The clay radon barrier carries a design saturated hydraulic conductivity of $7.6 \times 10^{-6}$ cm/s, based on site-specific laboratory testing, to ensure its radon attenuation and infiltration-barrier functions are achieved.<br>The uppermost rock mulch admixture layer is not subject to this specific compaction density standard, as it relies on particle interlock and gradation for long-term stability and erosion resistance.<br>The *Expanded Disposal Cell Design* report has been updated to clarify the 90 percent compaction standard for the applicable cover layers. Detailed execution specifications—including lift thicknesses, moisture conditioning requirements, and specific field QA/QC testing frequencies (e.g., nuclear densometer or sand-cone testing)—will be established in the Construction Quality Control (CQC) and Construction Quality Assurance (CQA) plans. As noted in the design report, these CQA/CQC plans will be submitted to the NMED for approval a minimum of 30 days prior to the beginning of construction of the clay liner. | |

<tr><td colspan="2">Total Cover Thickness</td><td>52 inches</td></tr>
</table></td><td></td></tr>
</table>

<table>
<tr>
<td>19</td>
<td>NA</td>
<td>NA</td>
<td>MECS “Comment 19” (March 6, 2026):<br><br>2025 Borrow Source Investigation - Please confirm that the available clean borrow material known is sufficient to complete the planned disposal cell cover as currently designed. Additionally, please confirm that, should the volume of contaminated materials (e.g., soil, building materials, etc.) exceed expectations, the remaining clean borrow material will still be adequate to cover the increased disposal cell volume.</td>
<td>EA confirms that the available clean borrow material is sufficient to complete the planned disposal cell cover as currently designed, with adequate contingency to accommodate potential increases in the final waste volume.<br><br>The comprehensive borrow source investigation conducted by EA evaluated Borrow Sources A, B, and C. The investigation concluded that Sources A and B were partially or fully depleted during previous construction. Therefore, Borrow Source C (an undisturbed 12.0-acre footprint) is the primary source for the earthen cover materials.<br><br>Based on the 52-inch optimized cover design (12-inch rock mulch admixture, 28-inch on-site soil, 12-inch compacted clay), the required borrow quantities and estimated available volumes are detailed below:
<table>
<tr><th>Cover Layer</th><th>Thickness</th><th>Estimated Required Volume (CY)</th><th>Primary Source</th><th>Estimated Available Volume (CY)</th></tr>
<tr><td>Rock Mulch Admixture</td><td>12 inches</td><td>31,833</td><td>30% AASHTO No. 1 gravel (Imported/Approved local source) & 70% on-site soil</td><td>Scalable to demand (commercial/imported rock)</td></tr>
<tr><td>On-Site Soil Cover</td><td>28 inches</td><td>70,620</td><td>Borrow Source C (Overburden sand and sandy clay)</td><td>Sufficient (Constitutes the upper strata across the 12-acre footprint)</td></tr>
<tr><td>Compacted Clay Barrier</td><td>12 inches</td><td>28,740</td><td>Borrow Source C (Subsurface clayey soils)</td><td>38,735 to 58,102 (Based on 2.0 to 3.0 ft of average recoverable thickness)</td></tr>
</table>
Contingency for Increased Waste Volume:<br><br>Should the volume of contaminated materials exceed current expectations (necessitating a larger disposal cell footprint or height), the borrow strategy provides adequate contingency:<br><br>1. Clay Barrier: Borrow Source C can yield up to approximately 58,102 cubic yards of suitable clay if excavated to an average recoverable thickness of 3.0 feet across the 12.0-acre footprint. This provides a substantial buffer beyond the current 28,740 CY requirement, accounting for over 100% contingency to cover material rejection, shrinkage, and cell expansion.<br>2. Soil Cover: The 28-inch soil layer utilizes the abundant sand and sandy clay overburden that must be stripped to access the deeper clays in Borrow Source C, providing ample material to scale with the cell dimensions.<br>3. Rock Mulch: Because the AASHTO No. 1 gravel fraction will be sourced from an approved local rock quarry or imported, its availability is not strictly limited by the site's earthen borrow footprint and can be scaled to meet any increased</td>
<td></td>

| 1 | NA | NA | **"SWQB Comment 1 – National Pollutant Discharge Elimination System (NPDES) Permit Status" (February 19, 2026):**<br>The Mt. Taylor Mine is covered under a Multi Sector General Permit (MSGP), #NMR05J02B, for industrial stormwater discharges currently issued by the U.S. Environmental Protection Agency. RGR should keep the stormwater pollution prevention plan (SWPPP) up to date to reflect conditions on the ground. | RGR will update the SWPPP to reflect current conditions as necessary. | |
| 2 | 4.4.6 | 39 | **"SWQB Comment 2 – Excavation and Disposal of Contaminated Soil" (February 19, 2026):**<br>Section 4.4.6 of the revised CCP describes that RGR is currently investigating all areas between its northern fenced boundary and the windblown area to identify the extent of any impacted areas, including the Marquez Canyon Arroyo to identify and dispose of any contaminated soil. The 2020 Radiological Surveys of Discharge Pipeline describes that soil excavation will be required for surface soils along the pipeline corridor or at Outfall 001 if Ra-226 concentrations exceed 6.8 pCi/g; A 2025 report demonstrates that materials have been removed along the pipeline corridor. Removal of contaminated soils, completion of the disposal cell, and completion of the site drainage upgrades will protect surface water quality. | RGR acknowledges this comment and concurs with the SWQB's assessment. RGR remains fully committed to executing the remediation activities outlined in Section 4.4.6 of the revised CCP, and investigations in the Marquez Canyon Arroyo and areas north of the fenced boundary will continue as described.<br>Although the pipeline outfall was previously characterized in 2013 (Appendix E of RGR, 2013a), RGR will include the Outfall 001 area in future closure characterizations to ensure any remaining radiological impacts are fully delineated. Based on these results, any soils exceeding the 6.8 pCi/g Ra-226 threshold will be excavated and properly placed in the expanded disposal cell once it is ready to receive material.<br>RGR agrees that completing these soil removals, finalizing the disposal cell, and upgrading the site drainage will effectively protect surface water quality. | |

| Comment Number | Section Number in CCP | Page From in CCP | Comment | Response | MMD Acceptance of EA Response |
|---|---|---|---|---|---|
| 3 | 2.3 and 4.6.2 | 8, 43, and 44 | **"SWQB Comment 3 – Surface Water" (February 19, 2026):**<br>Section 2.3 Surface Water of the revised CCP says that stormwater runoff retention structures will remain for livestock watering or will otherwise be re-directed to the existing drainage courses that would receive runoff. Stormwater retentions structures that were originally created in surface waters of the state or resulted in the impoundment of surface waters of the state meet the definition of surface waters of the state (see 20.6.4.7.S.5.b New Mexico Administrative Code for the definition of surface waters of the state). Section 4.6.2 of the revised CCP describes the original middle arroyo was largely filled in during site construction. Therefore, the stormwater runoff retention structures in this area are likely surface waters of the state and are subject to state surface water quality standards which include standards for livestock watering. RGR should conduct at least one sampling event to demonstrate that surface water in these retention structures meet the surface water quality standards for livestock watering, particularly for Radium 226 + Radium 228 which is 30 pCi/L (20.6.4.900 New Mexico Administrative Code). | RGR acknowledges the SWQB's comment and is committed to ensuring that any stormwater retention structures remaining to support the approved post-mining land use of livestock grazing are protective of human health and the environment and meet applicable regulatory requirements. Accordingly, RGR will conduct at least one surface water and sediment sampling event within the stormwater retention structures proposed to remain following reclamation prior to final closeout. Sampling will include analysis for constituents necessary to evaluate livestock watering use, including combined Radium-226 and Radium-228, which will be compared to the applicable surface water quality criterion of 30 pCi/L in 20.6.4.900 NMAC. The results will be provided to SWQB and MMD.<br>During active mining and closure operations, these stormwater retention structures will continue to function as engineered operational facilities for stormwater management, sediment control, and site remediation. Following completion of closure activities, including final grading, contaminated soil removal, and confirmation of water quality, RGR will coordinate with SWQB and MMD regarding the long-term management and regulatory status of any stormwater retention structures that remain as part of the approved post-mining land use.<br>Section 2.3.1 has been revised to reflect this sampling commitment and clarify the planned evaluation of the remaining stormwater retention structures during the closure process. | |
| 4 | 4.6.2 | 44 | **"SWQB Comment 4 – Arroyo Design and Monitoring" (February 19, 2026):**<br>The SWQB supports using the 500-year, 24-hour storm event to design the southern arroyo channel. SWQB recommends the portions of the arroyos that are in close proximity to reclamation areas be included in the Post Closure Monitoring Plan to ensure appropriate actions are taken to prevent potential impacts to the reclamation areas (and the arroyos) in the event the arroyos erode towards the reclamation areas. | RGR appreciates the SWQB's support for using the 500-year, 24-hour storm event as the design basis for the southern arroyo channel. However, given the limited area available within RGR-owned property to accommodate the proposed channel improvements, RGR is evaluating whether the 500-year, 24-hour design event can be practicably achieved within the available footprint. Condition 3(b) of the MMD-approved Revision 13-2 identifies a 100-year, 24-hour storm event as the design criterion for water diversion structures, or an alternative criterion approved by the MMD in consultation with other state or federal agencies. Accordingly, RGR proposes to evaluate the 100-year, 24-hour storm event as an alternative design basis for the southern arroyo channel.<br>RGR also concurs with the SWQB's recommendation to include those portions of the arroyos adjacent to reclaimed areas in the Post-Closure Monitoring Plan. Section 2.3 of the Post-Closure Monitoring Plan has been revised to include periodic inspections of these reaches to evaluate channel stability and identify erosion that could adversely affect reclaimed areas. If monitoring identifies erosion that could compromise reclaimed areas or drainage features, corrective actions will be evaluated and implemented as necessary. | |

# 1.0 INTRODUCTION

## 1.1 Background

Rio Grande Resources Corporation (RGR) owns and operates the Mt. Taylor Mine, located near San Mateo in Cibola County, New Mexico. The mine is currently on active status under Permit No. CI002RE, Rev 13-2 (Mine Permit), which was approved on December 29, 2017, by the New Mexico Mines and Minerals Division (MMD).

In 2022, RGR applied for a revision of its Mine Permit No. CI002RE (RGR, 2022b) to expand the Disposal Cell and update the existing Closeout/Closure Plan (CCP;RGR, 2013b). This revision application is submitted pursuant to the New Mexico Administrative Code (NMAC) regulations 19.10.5.505 (NMAC, 2001a) and 19.10.7.701 (NMAC, 2001c).

The CCP is required by 19.10.5.506 and 19.10.5.507 NMAC (NMAC, 2001a) to describe the measures and estimated costs for reclamation of the mine site for the designated post-mining land uses (PMLUs) at closeout/closure. This CCP was prepared following the guidelines presented in the *Closeout Plan Guidelines for Existing Mines* (MARP, 1996) that are part of the State of New Mexico Energy, Minerals and Natural Resources Department (EMNRD). of Mining Act Reclamation Program (MARP).

From 2022 to the date of this report, RGR and the various agencies have been working toward obtaining the updated Mining Act Permit CI002RE and Discharge Permit-61 (DP-61). As part of this ongoing process, RGR is submitting this update to the Closeout/Closure Plan (CCP) as requested in the comment letters cited below:

1. **September 7, 2022:** Surface Water Quality Bureau (SWQB) of the New Mexico Environment Department (NMED). *"Request for Review and Comment, Mt. Taylor Mine and Mill, Updated Closeout/Closure Plan, Revision 22-1, Cibola County, New Mexico Mining Act Permit No. CI002RE, Revision 22-1"* (NMED, 2022a).

2. **September 12, 2022:** Air Quality Bureau (AQB) of the New Mexico Environment Department (NMED). *"Request for Review and Comment, Mt. Taylor Mine and Mill, Updated Closeout/Closure Plan, Revision 22-1, Cibola County, New Mexico Mining Act Permit No. CI002RE"* (NMED, 2022b).

3. **November 15, 2022:** Hydrology Bureau of the New Mexico Office of the State Engineer (NMOSE). *"Review and Comments, Revision 22-1 to Mt. Taylor Mine, Permit No. CI002RE, Rio Grande Resources Corporation"* (NMOSE, 2022).

4. **April 14, 2023:** Mining Environmental Compliance Section (MECS) of the New Mexico Environment Department (NMED). *"New Mexico Environment Department (NMED) Comments, Updated Closeout/Closure Plan, Revision 22-1, Mt. Taylor Mine, Rio Grande Resources, Cibola County, New Mexico, New Mexico Mining Act Permit No. CI002RE"* (NMED, 2023).

5. **May 17, 2023:** Mining and Minerals Division (MMD) of the New Mexico Energy, Minerals and Natural Resources Department (EMNRD). *"Comments on Closeout/Closure Plan Mt. Taylor Mine, Rio Grande Resources Corporation, Mt. Taylor Mine, Cibola County, New Mexico, Permit Tracking No. CI002RE"* (MMD, 2023).

6. **February 1, 2024:** Hydrology Bureau of the New Mexico Office of the State Engineer (NMOSE). *"Review of Revision 22-1 to Mt. Taylor Mine, Permit No. CI002RE, Rio Grande Resources Corporation"* (NMOSE, 2024).

7. **June 20, 2024:** Mining and Minerals Division (MMD) of the New Mexico Energy, Minerals and Natural Resources Department (EMNRD). *"2nd Comment Letter, Mt. Taylor Mine, Disposal Cell Expansion and Update of Closeout/Closure Plan, Revision 22-1, Permit No. CI002RE"* (MMD, 2024).

8. **March 14, 2025:** New Mexico Mining and Minerals Division (MMD) of the New Mexico Energy, Minerals and Natural Resources Department (EMNRD). *"3rd Comment Letter, Mt. Taylor Mine, Disposal Cell Expansion and Update of Closeout/Closure Plan, Revision 22-1, Permit No. CI002RE"* (MMD, 2025).

9. **April 25, 2025:** Mining Environmental Compliance Section (MECS) in the Ground Water Quality Bureau (GWQB) of the New Mexico Environment Department (NMED). *"New Mexico Environment Department (NMED) Comments Round 3, Mt Taylor Uranium Mine Closeout/Closure Plan, Cibola County, New Mexico, Mining Act Permit No. CI002RE"* (NMED, 2025a).

10. **April 25, 2025:** Mining Environmental Compliance Section (MECS) in the Ground Water Quality Bureau (GWQB) of the New Mexico Environment Department (NMED). *"Request for Additional Information Round 3 Comments, Discharge Permit 61 Renewal and Modification Application, Mt. Taylor Mine, San Mateo, New Mexico"* (NMED, 2025b).

11. **February 19, 2026:** New Mexico Environment Department (NMED). *"NMED Memorandum, Request for Review and Comment, Mt. Taylor Mine, Cibola County, New Mexico Mining Act Permit No. CI002RE"* (NMED, 2026a).

12. **March 6, 2026:** Surface Water Quality Bureau (SWQB) of the New Mexico Environment Department (NMED). *"NMED Surface Water Quality Bureau (SWQB) Memorandum, New Mexico Environment Department (NMED) Comments, Mt Taylor Uranium Mine, Updated Closure Closeout Plan, Mining Act Permit No. CI002RE"* (NMED, 2026b).

13. **March 18, 2026:** New Mexico Mining and Minerals Division (MMD) of the New Mexico Energy, Minerals and Natural Resources Department (EMNRD). *"Comment Letter, Mt. Taylor Mine, Update of Closeout/Closure Plan, Revision 22-1, Permit No. CI002RE"* (MMD, 2026).

The CCP was initially submitted in 1998 by RGR (RGR, 1998) as a revision to its existing Mine Permit No. CI002RE (RGR, 1994b) in accordance with the New Mexico Mining Act of 1993 (New Mexico, 2005), Section 69-36-1, Section 69-36-11B(3) and (4), and the New Mexico Mining Act Rules subparts 506.A and 506. B of 19.10.5 NMAC (NMAC, 2001a).

The NMED Water Quality Control Commission (WQCC), through 20.6.2.3107 A (11) NMAC (NMAC, 2018b), as enforced by the MECS of the GWCB, also required a CCP under DP-61 (NPDES, 1979). DP-61 was initially approved in 1979, modified and renewed in 1984 (NPDES, 1984) and 1989 (NPDES, 1989), and amended to include a CCP in 1995. Both the Mine Permit and the DP-61 require reclamation of some of the mine facilities and financial assurance (FA) to cover the cost of such reclamation. Because the CCP and DP-61 have common elements and similar FA requirements, MMD and MECS agreed that RGR could submit one CCP, including one cost estimate that satisfies the requirements of both agencies, with MMD taking the lead in coordinating the regulatory review and approval process, RGR submitted its CCP for existing conditions applicable to the mine site during standby in July 2012 (RGR, 2012).

In April 2013, RGR submitted an updated CCP (RGR, 2013a) for the mine after returning to active status. Energy, Minerals, and Natural Resources Department (EMNRD)/MMD accepted the 2013 CCP revision (RGR, 2013b) and MMD approved and issued an active status permit (CI002RE, Rev 13-2) on December 29, 2017 (MMD, 2017). This updated CCP is for revision of the approved 2013 CCP (RGR, 2013b) to reflect the status of the Mine Permit.

The original Mine Permit CCP (RGR, 1998) and the DP-61 closure plan renewal (NPDES 1998) anticipated that the primary post-mining land use (PMLU) of the mine site and most facilities would be a water supply project (WSP). Although the WSP remains a feasible PMLU, the previous business agreements for the WSP have expired. Thus, the WSP was not included in either the 2012 CCP update (RGR, 2012) nor the 2013 CCP (RGR, 2013a, 2013b) update and is also not included in this revision of the CCP.

The mine remains in active permit status. However, in 2019, RGR decided not to return the mine to production and to begin some closeout/closure activities included in the 2013 CCP (RGR, 2013b), which is permissible under the Mining Act (New Mexico, 2005). Accordingly, this submittal has been prepared to revise the 2013 CCP (NMED, 2013b) to reflect the existing land disturbances and the mine facilities, both those already removed and those remaining. This CCP describes the measures that will be taken to reclaim the disturbed land for post-mining land use and to satisfy the requirements of relevant environmental standards.

The following sections contain a description of the mine site and mining-related disturbances (Section 2.0); PMLU and related ecosystems (Section 3.0); completed and pending closeout/closure measures to achieve the PMLU (Section 4.0); and environmental monitoring, environmental standards, and permits required for closeout/closure (Section 5.0). Section 6 addresses the CCP schedule. The updated cost estimate for closeout/closure of the mine is discussed in Section 7.0. The revised cost estimate will be completed and submitted 60 days after CCP approval.

## 1.2 Project Description

RGR owns and operates the Mt. Taylor Mine in Cibola County, New Mexico, Section 24, T13N, R8W, NMPM (Figure 1-1). The mine site is 1/2-mile northeast of the Village of San Mateo and is accessible New Mexico State Route 605.

The mine facilities at the ground surface are shown in Figure 1-2. No mill was ever constructed or operated within the permit area. Since 2020, RGR has removed some surface facilities for closeout/closure.

The existing Mt. Taylor Mine units were described in the Mine Permit Application of December 1994 (RGR, 1994b). The mine permit areas consist of 4,006.7 acres (Figure 1-3), and the mine surface facilities are located on 285.6 acres, of which approximately 148 acres are disturbed land.

The disturbed land surface in the permit area consists of:

- Service and Support Facilities
- Mine Water Treatment Area
- Ore Stockpile Pad
- Existing Disposal Cell
- Storm Water Retention Ponds (North and South)
- Site Access Roads

The existing facilities and those already removed as of September 2026 are shown in Figure 1-2b. Permits other than the Mine Permit are listed in Table 1-1. Detailed locations and descriptions of deep wells are shown in Figure 1-4 of this CCP.

An inactive 24-inch diameter Treated Water Discharge Pipeline previously extended 4.3 miles from the Mine Water Treatment Unit (MWTU) area north to the outfall point in San Lucas Canyon north of the mine (Figure 1-3). RGR completely dismantled and removed this pipeline in 2024 and 2025; all associated corridor disturbances were successfully re-contoured and revegetated in the fall of 2025.

A maintained gravel access road (County Road 334) bisects the mine site. This is a state road and right-of-way, maintained by Cibola County, which provides public access to the west edge of the Cibola National Forest; it is not part of the Mine Permit area, but is an affected area (Section 4.4.5.). Any soils with levels exceeding the approved radium limit of 6.8 pCi/g will be removed during closeout/closure. Technical criteria governing these cleanups are detailed in Section 4.4.6.

An adobe ruin remains on the small hill east of the south storm water pond (Figure 1-2b). This feature was not disturbed by, or used in, mining and will be left in place.

The Underground Mine Unit, consisting of the underground workings, shafts, and conduits, has no surface disturbance other than that included in the Service and Support Facilities Unit (shaft collars and connecting ventilation openings). The mine extracted uranium ore using room-and-pillar and stope mining methods. Mining was conducted on a single level (Westwater Formation ore horizon), approximately 3,100 ft below the surface. These mine workings were connected to two approximately 3,300-feet deep shafts via shaft stations. Several hydrostratigraphic units were penetrated by the shafts, requiring three sets (phases) of deep wells for local dewatering to access the ore body (Figures 1-4 and 1-5).

## 1.3 Project History

Prior to 1971, when Gulf Mineral Resources Corporation acquired the property, no mining had occurred within the permit area of the Mt. Taylor Mine. However, exploratory drilling and construction of associated access roads occurred prior to 1971. A December 17, 1997, U.S. Forest Service letter addressing reclamation of these historical drill pads and access roads recommended that unused areas be closed to vehicle access and allowed to naturally revegetate rather than be recontoured because additional disturbance would adversely affect existing vegetation (Appendix L).

### 1.3.1 Mine Development

The Mt. Taylor Mine was developed in the 1970's by Gulf Mineral Resources Company (Gulf). Two, approximately 3,300-foot-deep mine shafts were constructed using traditional drill-and-blast methods with progressive liner construction to gain access to the ore zones. Shaft sinking began in 1976 and was completed in 1979. During shaft advancement, dewatering of the mine was accomplished by using a series of dewatering wells (DW Wells) constructed in three phases (Figures 1-4 and 1-5). Once the shafts were completed, development drifting into the orebody began. During development, dewatering of the mine was accomplished using pumps within the shaft and workings.

### 1.3.2 Mine Production

Gulf started production in 1980, after the orebody was sufficiently developed. Production continued until September 1982, when the market price of uranium fell dramatically, resulting in the temporary cessation of production by Gulf. Mine pumps continued dewatering the mine during this shut-down period. Ownership was transferred to Chevron Resources Company in 1985 when the two companies merged. Chevron produced ore from the mine from 1986 to 1990, when it suspended mining of uranium ore, again due to low market prices for uranium.

The mine historically produced uranium using conventional underground mining methods from ore zones of the Morrison Formation at depths of more than 3,000 ft bgs. Approximately 675,085 tons of ore and approximately 698,000 tons of waste rock have been mined (RGR, 1994a). The ore was shipped off-site for milling. Overlying formations, including the water-bearing Dakota Sandstone, were penetrated by the shafts, but no mining of ore was conducted in those formations.

Waste rock from shaft sinking (shaft muck) and from mine development was placed in an on-site stockpile, located at the southwest corner of the waste rock pile. The shaft muck was found to meet

the criteria of clean materials (radioactive components at or below background values, see Appendix D.1) and was subsequently added to the disposal cell.

The mine has not produced uranium since RGR purchased the property because of the continued low market price for uranium and the high cost of reactivation. Facility descriptions remain unchanged from those provided in previous renewals of this plan.

### 1.3.3 Mine De-Activation

Chevron Resources Corp. ceased mining activities at the Mt Taylor Mine in January 1990 due to low uranium market prices. RGR acquired the mine property in 1991 and maintained the mine in a ready status in anticipation of improving uranium market conditions.

### 1.3.4 Mine Permitting

RGR submitted its application for an Existing Mine Permit in December 1994, shortly after the New Mexico Mining Act was passed and the rules went into effect. The MMD approved the Mt. Taylor Mine Permit No. CI002RE as an existing mine operation on July 28, 1995 (MMD, 1995). On December 18, 1998, the MMD approved the CCP and FA for the mine (MMD, 1998).

RGR submitted its first application for standby status of the Mt. Taylor Mine on March 25, 1999 (RGR, 1999). MMD approved standby status on October 7, 1999, under permit revision 99-1 (MMD, 1999). From 1999 to 2017, the mine was in standby status due to the depressed uranium market.

Anticipating recovery of the uranium market, RGR submitted an application in 2013 to revise the Mine Permit from standby to active status (RGR, 2013a; RGR, 2013b). Since December 29, 2017, the mine has been in active status. However, in 2019, RGR decided that the uranium market was not recovering sufficiently to justify resuming production of the Mt. Taylor Mine, so closeout/closure activities began.

### 1.3.5 Mine Water Pumping, Treatment, and Discharge

To gain access to the ore zones during mine development, dewatering (depressurizing) wells were drilled and operated in stages. The primary function of these wells was to reduce the water pressure on the shaft as it was constructed. Pumping water from these dewatering wells began in the early 1970's and ceased by 1978. Locations and descriptions of these dewatering wells within the mine area are shown in Figure 1-4. A typical geologic section and typical well construction are shown on Figure 1-5. Shallow monitoring wells were installed to track the effects on shallow water resources from the sewage lagoon leakage or the diesel spill contamination (Figure 1-6, Table 1-3).

During mining operations in the late 1970’s and through the 1980’s, the mine was dewatered via underground pumps and piping. The water was pumped to the MWTU facility on the surface, where it was treated to reduce radium concentrations before discharge. The treated water was then discharged through a 24-inch diameter, 4.3-mile-long pipeline (Treated Water Discharge Pipeline). This pipeline mainly crossed private land, except for approximately a three-quarter-mile portion on US Forest Service land. The pipeline terminated at the outfall in San Lucas Canyon north of

the mine (Figure 1-3). The treated water was discharged under the now-terminated National Pollutant Discharge Elimination System (NPDES) Permit No. NM0028100 (NPDES, 2016) into the ephemeral drainage of San Lucas Canyon. Historical investigations completed between 2013 and 2020 evaluated soil, sediment, surface water, and groundwater conditions at Outfall 001 and at selected downstream locations within the San Lucas drainage to assess potential impacts from historical mine water discharges. These investigations generally concluded that historically treated mine water discharges had not resulted in significant impacts to downstream soils or groundwater; however, subsequent radiological surveys identified localized areas requiring additional evaluation as part of mine closure. A summary of the historical investigations and the planned characterization activities for Outfall 001 is provided in Appendix M, *Outfall 001 Historical Summary and Planned Characterization* (EA, 2026e).

Seven observation wells were installed for monitoring drawdown during the initial dewatering of the mine (Figures 1-4 and 1-7). Observation wells SM 24-89, SM 24-43, and SM 24-38, which are completed in the Westwater formation, are in the mine area near the production shaft (Figure 1-4). One of these observation wells, SM 24-23E, is in the mine area near dewatering well DW-8 and is competed in the Tres Hermanos/Dakota formation. The three other wells are located outside of the mine area at locations shown in Figure 1-7. These observation wells have not been used since operations ceased in the 1980's. Water levels in the dewatering and observation wells are listed in Table 1-2.

## 1.4 Other Permits

RGR maintains several permits that are relevant to the closeout/closure of the Mt. Taylor Mine. In addition to the Mine Permit and DP-61, the other permits related to the mine are listed in Table 1-1.

The NPDES Permit No. 0028100 (NPDES, 2016) was terminated by the U.S. Environmental Protection Agency (EPA) in 2021 because it was no longer required. The Mt Taylor Mine facility has not discharged through Outfall 001 since the early 1990's.

Radioactive Material License SO043-14 (NMED, 2020) was terminated in 2021 because it was no longer required. The sources covered under the license were no longer needed and were disposed.

There are no stationary sources with potential emissions of regulated contaminants associated with closeout/closure activities, so there are no air quality permit requirements for closeout.

The U.S. Forest Service Special Use Authorization (MOT220) for the treated water discharge pipeline was terminated on November 25, 2025, following completion of pipeline removal. No additional authorizations associated with the former treated water discharge pipeline are anticipated for mine closeout/closure.

No other permits beyond those listed in Table 1-1 and those just discussed above are required for closeout/closure of the Mt. Taylor Mine.

# 2.0 SITE CHARACTERISTICS

## 2.1 Site Climate

The climate and baseline air quality of the permit area are described in the *Environmental Site Assessment* (RGR, 1994a) and the *Permit Application* (RGR, 1994b). The climate is semi-arid, like most of the state, but the elevation (about 7,300 ft above MSL) and orographic effects of Mt. Taylor cause low winter temperatures and frequent high winds that impose some limitations on post-mining land uses and ecosystems. In particular, the climate of the site is not well-suited to crop production other than hay, but it has historically allowed livestock grazing. Rainfall is not sufficient to support forest within the area of the surface facilities, where most disturbance has occurred.

## 2.2 Site Geologic Setting Summary

The geologic setting of the mine has been described in detail in the *Environmental Baseline Study* prepared by New Mexico Environmental Institute (NMEI) in 1974 (NMEI, 1974) and the *Environmental Site Assessment* submitted in 1994 (RGR, 1994a). The following summary is derived from those, and other reports. The geologic section is illustrated in Figure 2-1.

The deepest geologic formation encountered in the Mount Taylor mine shaft is the Jurassic-age Morrison Formation. The Morrison Formation includes the following members, in ascending order: the Recapture Creek, the Westwater Canyon, and the Brushy Basin. Recapture Creek member occurs at a depth between 3,240-3,300 ft bgs in the mine shaft pilot well. This member grades vertically into the overlying Westwater Canyon member. The Westwater Canyon member is variable in thickness owing to lensing and vertical gradations into both the Brushy Basin and Recapture Creek members. At the mine site, the Westwater Canyon is divided into Upper and Lower units by a persistent shale unit. The lower sandstone unit is about 60 to 70 ft thick, while the upper sandstone unit is approximately 100 ft thick in the mine shaft area. These two sandstone units contain most of the uranium ore reserves of the mine. The Brushy Basin member conformably overlies and interfingers with the Westwater Canyon member. It is approximately 80 ft thick and consists predominantly of shales and claystones at the mine shaft.

Between the ore-bearing Morrison Formation and the ground surface is a sequence of sedimentary units approximately 2,950 ft thick, starting with the Dakota Sandstone, which unconformably overlies the Brushy Basin. The Dakota is approximately 50 to 60 ft thick and is only slightly mineralized and not mined at the Mt. Taylor Mine. The Dakota conformably intertongues with the overlying Mancos Shale.

The overlying Mancos Shale, nearly 900 ft thick, is composed chiefly of dark-gray, calcareous, marine clay shale but does contain interspersed sandstone units. The lowermost portion of the Mancos Shale contains three sandstone units that have been referred to as the Upper, Middle, and Lower Tres Hermanos Sandstones. These sands are 72 ft, 45 ft, and 118 ft thick, respectively, at the mine shaft pilot well (McGlothin, 1972).

Above the Tres Hermanos Sandstones, the Manco Shale extends up to the base of the Gallup Sandstone at approximately 2,050 ft bgs. The Gallup Sandstone consists of two separate sandstone

units separated by 130 ft of dark gray shale. Overlying the Gallup Sandstone is the Crevasse Canyon Formation which includes, in ascending order, the Dilco Coal, the Stray Sand, the Mulatto Tongue of the Mancos Shale, the Dalton Sandstone, and the Gibson Coal. The Crevasse Canyon Formation is conformably overlain by the Point Lookout Formation.

The Point Lookout Formation is the basal unit of the Mesa Verde Group and it is typically encountered between 700 and 850 ft bgs at the mine site. In the vicinity of the mine, this unit is separated into two units by the Satan Tongue of the Mancos Shale. The upper unit, referred to as the Point Lookout Sandstone, is the main body, and it is typically 110 to 130 ft thick. The lower unit is the Lower Hosta Tongue, a transgressive marine beach sandstone that is between 80 to 100 ft thick. Both units merge along the southern margin of the basin to a combined unit approximately 250 ft thick. The Lower Hosta Tongue is of limited areal extent, pinching out 30 miles northeast of its outcrop. The Point Lookout Sandstone consists of a sequence of thick-to very thick-bedded, very fine-to medium-grained, locally cross-bedded sandstone. The Point Lookout/Hosta (PLH) aquifer provides the domestic water supply for both the mine and the Village of San Mateo.

The Menefee Formation is the uppermost geologic unit present at the mine. It forms uneven slopes around the mine and near the Village of San Mateo. The formation is composed of interbedded pale yellowish-brown silt stone, fine to medium grained sandstone, gray shale, carbonaceous shale, and thin coal beds. Its thickness at the mine shaft is approximately 767 ft (NMEI, 1974). Mine water treatment pond basins were excavated into the Menefee, and both the manway/vent and production shafts are collared in this formation.

Deposits of Quaternary age exposed in the area consist of unconsolidated talus, alluvial, and eolian sediments. Talus, landslides, and black lava blocks cover extensive areas on the slopes adjacent to the high basalt-covered mesas to the south, southwest, and east of the mine. Clay, silt, sand, and gravel alluvial lenses underlie the valleys, as well as the lower topographic slopes (NMEI, 1974).

## 2.3 Site Hydrology Summary

The hydrologic conditions of the mine and impacts from mining have been described in detail in the Baseline Study (NMEI, 1974) and the Environmental Site Assessment (RGR, 1994a). The following summary of the surface and groundwater hydrology from those reports and updates from more recent observations and studies is provided as the basis for proposed closeout/closure measures.

### 2.3.1 Surface Water

Two main surface drainage systems collect both bedrock seepage water and storm water run-off in the vicinity of the mine. The primary surface water course is San Mateo Creek, located one-half mile south of the mine. This perennial stream is fed with numerous springs in the San Mateo Canyon area but disappears into the stream bed approximately two miles beyond the Village of San Mateo. During spring peak run-off and after heavy rainstorms, the surface flow may occasionally extend for a brief period farther down San Mateo Creek. Surface water runoff within the permit area occurs only after heavy precipitation on or upstream from the site.

The second main drainage system is the Marquez Arroyo ephemeral steam, located immediately north of the mine. This deeply incised arroyo collects water during the infrequent heavy rainstorms, but otherwise it is dry throughout the year. Low-flow springs are located at higher elevations feeding this drainage, but their total flow has never been large enough to be measurable at the mine's elevation. Marquez Arroyo flattens out, and surface flow dissipates into the alluvium about one-half mile west of the mine.

Constructed during mine development in the 1970's, diversion ditches and below-grade collection systems intercept and channel runoff originating on the site to storm water retention ponds where water is evaporated. These ditches replace three shallow ephemeral drainage courses that existed prior to mine development (Figure 2-2). Storm water originating directly on the mine site area is channeled into culverts and storm water pipes, which flow into storm water retention ponds and evaporates.

During the 2018–2019 mine reactivation phase, the facility's drainage infrastructure underwent a series of upgrades:

1. Runoff from the service and support area previously directed into mine water treatment Pond #2 has been diverted into a replacement storm water collection system (re-constructed 2018) along the county road that discharges to the South Storm Water Pond (SSWP).
2. Runoff from the east and north slopes of the Waste Rock Pile now collects in a storm water collection system that discharges into the SSWP (Appendix A Drawing Sheet CL 14), which was completed in 2019.

The storm water runoff retention structures are designed to contain not less than the 100-year storm runoff and hold the water for evaporation. Following final closeout, those diversion ditches and retention structures that support the post-mining land use (PMLU) will remain in use for stock watering; otherwise, runoff will be re-directed to existing drainage courses that naturally would receive runoff from the site (Appendix A Drawing Sheet CL 14).

Per 20.6.4.7.S(5)(b) NMAC, storm water retention structures that were originally created in surface waters of the state or resulted in the impoundment of surface waters of the state meet the definition of surface waters of the state. Because portions of the operational area and the associated storm water retention structures overlay the historical middle arroyo channel, these water bodies may be subject to state surface water quality standards, including the protective standards for livestock watering upon final site closeout.

To demonstrate that the surface water in these structures is safe for livestock consumption and satisfies state standards, RGR will conduct at least one comprehensive surface water and sediment characterization sampling event within the retention ponds prior to final site release. This sampling event will verify that the water quality meets the state livestock watering standards, with particular emphasis on ensuring that Radium-226 + Radium-228 concentrations comply with the 30 pCi/L maximum limit established under 20.6.4.900 NMAC. Throughout the active closure and earthwork execution phases, these ponds will continue to be managed as

active industrial containment and remediation facilities. The final jurisdictional status of the remaining stock watering ponds under 20.6.4 NMAC will be determined in coordination with the Surface Water Quality Bureau (SWQB) following the submittal of the closure validation data.

### 2.3.2 Groundwater

Aquifers and the groundwater conditions in the mine area are described in detail in the Baseline Study (NMEI, 1974), and in aquifer test reports (McGlothin, 1972), the Water Resources Report (Geohydrology Associates, Inc., 1994), and the Site Conceptual Hydrogeologic Model (EA, 2025b). The following summary of groundwater hydrology from those reports and updates from more recent observations and studies are provided as the basis for proposed closeout/closure measures. Aquifers capable of yielding large quantities of groundwater occur in some Cretaceous formations and in the Jurassic Morrison Formation, where the uranium ore bodies are found.

Several aquifers are intersected by the mineshafts and were affected by the mine dewatering. Key aquifer systems of interest include the Point Lookout/Hosta (PLH), Tres Hermanos/Dakota (THD) and the Westwater Canyon member of the Morrison Formation (WWC). Groundwater from these strata was removed by pumping a series of dewatering wells during mine shaft advancement until 1978 (Figures 1-4 and 1-5) and then by underground mine pumps into 1990 to dewater the ore bodies. The underground mine pumps were shut off in June 1990, after mining operations were suspended, and the mine has subsequently flooded as groundwater levels recovered. The mine water derived from the Westwater Canyon member has concentrations of uranium, radium, sulfate, and TDS that exceed current drinking water standards (Table 2-1).

The shallowest aquifer capable of sustaining a potable water supply in the mine area, the PLH, has a potentiometric surface at a depth of approximately 460 to 610 ft bgs (Table 1-2), and the aquifer has a large flow potential. The Village of San Mateo and the mine have wells reaching depths between 650 to 1190 ft and are completed within the PLH. The mine began using this water in 1972, whereas the San Mateo village water well, located at 35° 19’ 56.14” N, 107° 39’ 02.53” W, was drilled in 1976 by Gulf and serves approximately 200 residents. The geologic cross-section indicates that the Point Lookout Sandstone is separated vertically from the surface and alluvium by over 650 ft of shale and sandy shale sequences (Figure 2-1) in the Menefee Formation, minimizing the possibility of any shallow Menefee or alluvial aquifer groundwater discharging to the PLH aquifer.

As shown in the second quarter of 2026 dewatering well groundwater sampling results (EA, 2026a), the quality of the PLH aquifer generally meets the WQCC water standards with occasional exceedance of the fluoride standard and some low-level detections of petroleum hydrocarbon compounds (Table 2-2). Engineering Analytics (EA) prepared an assessment of fluoride levels measured in wells and springs in the area that are completed within or discharge from the shallow (alluvial and Menefee) and deeper (PLH through the THD aquifers and concluded that natural occurrences of fluoride commonly exceed the WQCC standard of 1.6 mg/L (EA, 2025b).

The Environmental Baseline Study (NMEI, 1974) includes a list of other shallow water wells, most of which are clustered in and around San Mateo. Six wells (three hand-dug) are in the alluvium, less than 100 ft deep, and nine wells produce from the Upper Menefee Formation from

120 to 336 ft deep. Some of these wells may still be used for watering livestock, but several of them were abandoned when the PLH water well was drilled for village use by Gulf.

The alluvial and shallow portions of the Menefee Formation are unconfined aquifer systems that yield small amounts of water in the local area. Water levels vary from 35 to 90 ft bgs. The alluvial sediments vary from 0 to 65 ft thick at the mine site. The Menefee Formation is typically over 750 ft thick and is comprised of interbedded shales, claystones, and sandstones, which provide a confining layer to the underlying Point Lookout Sandstone (Figure 2-1).

Perched groundwater occurs in some locations in the mine area. A discontinuous perched groundwater zone occurs at approximately 12-25 ft bgs, located within the Waste Rock Pile and paleochannels. Alluvial groundwater occurs at the alluvial/bedrock contact at approximately 45-60 ft bgs primarily in paleo-arroyos within the operational area of the mine and in shallow, low-volume saturated zones elsewhere in the Upper Menefee.

A geophysical study was conducted in 2020 (Willowstick, 2020) across the southern half of the mine site. This study concluded that preferential groundwater flow paths exist beneath the Waste Rock Pile and the operations area. The primary preferential groundwater flow paths identified in the study overlap the paleo-arroyo channels that were filled in as part of the mine site development. The study also identified several areas of perched water within the Waste Rock Pile. In late 2020, an additional site investigation was conducted, with installation of seven new monitor wells located in the preferential flow paths identified in the Willowstick study (Ensero, 2021b). These new wells were completed in water-bearing siltstones and sandstones within the Upper Menefee just below the alluvium/bedrock contact. One background monitoring well, MW-1C, was installed in the southeast portion of the mine site. Alluvial and Menefee monitoring and recovery well locations are shown on Figure 1-6 and listed in Table 1-3.

Recharge to the alluvial and Upper Menefee groundwater at the mine site comes from the Menefee Formation east of the mine site, historic seepage from a former sewage lagoon and meteoric waters that recharge occurs primarily through paleochannels from seeps and possibly springs along the (now) subcrop of Menefee sandstone beds that were covered when Gulf conducted extensive cut and fill of the mine surface during 1976-1980. The paleochannels were the drainage courses for discharge from those springs, as well as surface runoff from the mine site and the mesa above the mine site. Alluvial and Upper Menefee groundwater flows west to northwest through the mine site.

### 2.3.3 Site Conceptual Hydrogeologic Model

A site conceptual hydrogeologic model of the Mt Taylor mine site is presented that provides a synthesis of available site geologic and hydrologic information. More detailed description of the deeper aquifer systems is provided in a report submitted by EA in 2025 (EA 2025b).

The deepest aquifer of interest with respect to the mine site is within the Westwater Canyon (WWC) member of the Morrison Formation (Fm). This aquifer occurs at a depth of approximately 3,100 to 3,200 ft bgs, is between 120 and 180 feet thick, and was the ore-bearing unit that was mined for uranium at Mt Taylor. The WWC aquifer can transmit large amounts of groundwater. During the dewatering of the mine from 1979 to 1990, the WWC aquifer produced water at

sustained rates between 3,000 and 4,000 gallons per minute (gpm). Dewatering activities ceased in 1990.

Water level elevations within the WWC dewatering wells are generally between 6,580 and 6,590 ft amsl. Based on these potentiometric data, the ambient groundwater flow direction is to the northwest (Figure 2-3). Water levels within the WWC aquifer have largely recovered to pre-mining levels.

Water quality of the WWC aquifer measured prior to mining operations typically exceeded secondary drinking water EPA standards for sulfate and TDS, and NMED WQCC standards for total radium. Because of its depth and water quality, and the fact that there are better, shallower alternative sources, the WWC is not considered a potable water supply in the local area.

The WWC lies between the Recapture Creek and Brushy Basin members of the Morrison Fm, both of which are considered aquitards in the area of the mine site because they consist predominantly of finer grained units of shales, claystones, and mudstones, with thin interbedded sandstones. Between the Morrison Formation and ground surface is a sequence of sedimentary units approximately 2,950 ft thick.

Directly above the Morrison Fm, is the Dakota Sandstone, approximately 50 to 60 ft thick. The Dakota Sandstone is considered a regional aquifer, although it is not used for water supply locally, primarily because of its depth of around 2,900 ft bgs. Overlying the Dakota Sandstone is the Mancos Shale. Within the lowermost portion of the Mancos Shale are three sandstone units collectively referred to as the Tres Hermanos. The Dakota Sandstone is separated from the overlying Tres Hermanos by a relatively thin (less than 15 ft) shale layer and from the underlying WWC aquifer by the shaley Brushy Basin Member. Water level elevations for the dewatering wells are generally between 6,545 and 6,725 ft amsl. Water level data suggest that the Dakota and Tres Hermanos aquifers, and possibly the WWC aquifer, may be hydraulically connected. Limited potentiometric data for the Dakota/Tres Hermanos aquifers suggests a south to southeasterly groundwater flow direction (Figure 2-4), which is opposite to that of the WWC aquifer. However, the data may not be representative because many of the dewatering wells that are screened within the Dakota/Tres Hermanos aquifers are also screened across other shallower aquifers.

Most of the Mancos Shale is characterized as a thick sequence of predominately marine shales. There is an approximately 550 ft section of Mancos Shale separating the Tres Hermanos Sandstones from the overlying Gallup Sandstone. The Gallup aquifer (which includes the Lower and Upper Gallup Sandstones) occurs from approximately 1,740 to 2,010 ft bgs at the mine shaft. The Mancos Shale interval provides a significant confining layer between the Tres Hermanos and Gallup aquifers. Pre-mining water level data collected from a shaft pilot well confirmed the hydraulic isolation between the Tres Hermanos and Gallup aquifers (McGlothin, 1972). There is insufficient data to estimate the potentiometric surface of the Gallup aquifer system (which includes the Lower and Upper Gallup Sandstones).

Overlying the Gallup Sandstone is the Crevasse Canyon Fm, which is approximately 690 ft thick at the mine shaft. The Crevasse Canyon Fm consists of the following units in ascending order (approximate depth encountered in the mine shaft in parentheses in ft bgs): Dilco Coal (1,720),

Stray SS (1,640), Mulatto Tongue of the Mancos Shale (1,297), Dalton SS (1,138), and Gibson Coal (1,013). The formation is composed primarily of fine-grained sandstone, siltstone, and shale with coal present in the Gibson and Dilco Members. The sandstones within these units are typically fine-grained and are limited in areal extent but could potentially provide a localized water supply. The Gipson Coal is overlain by the Lower Hosta Tongue of the Point Lookout Sandstone. There are no dewatering or observation wells that are completed only within the Gallup Sandstone, or the Crevasse Canyon Fm, or any of its subunits.

The PLH aquifer is typically encountered between 700 and 850 ft bgs. At the mine site, the PLH aquifer is separated into two units by the Satan Tongue shale. The upper unit is the main body, commonly referred to as the Point Lookout Sandstone. The upper unit is typically 130 ft thick. The lower unit is the Lower Hosta Tongue, a transgressive marine beach sandstone that is approximately 100 ft thick. Testing in the mine shaft pilot well indicated relatively higher permeability within the PLH aquifer. The PLH provides a local water supply to the village of San Mateo and to the Mt Taylor mine. Water level elevations within the PLH dewatering wells are between 6755 and 6880 ft amsl. Potentiometric data indicates a southerly groundwater flow direction for the PLH aquifer (Figure 2-5).

The projection of the PLH aquifer potentiometric surface through the shaft location is approximately 6,785 ft amsl. The water level elevation within the shaft (which is open to the WWC aquifer) is approximately 6,564 ft amsl. The potentiometric surface of the PLH aquifer (Figure 2-5) is more than 200 ft higher than in the WWC aquifer (Figure 2-3) at the shaft location. No breeches or failures have been identified in the shaft where it penetrates the PLH. The large difference in the potentiometric surfaces clearly indicates that the concrete shaft lining is effectively separating groundwater in the WWC aquifer from the PLH aquifer.

Water quality of the PLH is generally within NMED WQCC standards although there are local exceedances of fluoride (Table 2-2). Additionally, petroleum hydrocarbons (PHCs) in the form of Light Non-Aqueous Phase Liquids (LNAPLs) and some dissolved concentrations were detected in two of the PLH dewatering wells (DW-3 and DW-10). LNAPLs were also detected in one THD well, DW-11. Corrective actions have reduced dissolved concentrations to below NMED standards for all PHCs and removed the LNAPLs, with the exception of naphthalene in DW-11. Investigation into the source of those constituents is ongoing, and monitoring of the PLH and THD dewatering wells is ongoing.

The Menefee Fm is the shallowest geologic unit present at Mt Taylor mine site and is found in outcrops and in the shallow subsurface. The Menefee Fm is typically greater than 750 ft thick and consists of interbedded siltstone, fine- to medium-grained sandstone, gray shale, carbonaceous shale, and thin coal beds. This thick sequence of relatively low permeability sediments provides a confining layer to the underlying PLH aquifer.

The shallow portions of the Menefee Fm yield small amounts of water in the local area. Water levels vary from 35 to 90 ft bgs. Potentiometric data indicates a generally west to northwest flow direction across the mine site within this hydrogeologic unit (Figure 2-6).

The alluvial sediments vary from 0 to 60 ft thick at the mine site and are typically located along drainages and within paleo-arroyos. Alluvial groundwater occurs locally as discontinuous, thin saturated zones at the alluvial/Menefee Fm contact at depths of 45-60 ft bgs within the operational area of the mine. A discontinuous perched groundwater zone occurs at approximately 12-25 ft bgs located within the Waste Rock Pile and paleochannels.

Groundwater impacts from mining have been identified within the perched, alluvial, and upper Menefee Fm groundwater systems. Table 2-2(a) summarizes the exceedances that were observed in the second quarter sampling event (EA, 2026b). Additional field investigation and characterization to delineate the nature and extent of those impacts is in progress at the time of this report.

## 2.4 Mine Units

Mt. Taylor Mine was an underground mine, with the ore bodies present over 3,000 ft bgs and supported by a surface facility. Refer to the Permit Application (RGR, 1994b) for details of the mine facilities. Ore was mined by conventional drill-and-blast methods, hoisted to the surface in ore skips via shafts, and transported offsite for milling.

A worst-case subsidence analysis was performed in support of the 1994 Permit Application (RGR, 1994b). Even with the assumed case of 100% extraction of ore, which would not be physically possible, no subsidence would reach the ground surface and would be limited to 300 ft above the mine workings. During previous mining operations, approximately 1.3 million tons of ore and waste rock were extracted from the ore bodies in the Morrison units.

Using best current practices of room-and-pillar mining with backfilling, subsidence would be limited to heights less than one room width above the room, leaving overlying aquifers and ground surface unaffected. Therefore, upon closeout, underground workings (the Underground Mine Unit) will be abandoned, and shafts plugged at the surface.

Mine units identified in the 2013 Mine Permit renewal application (RGR, 2013b) include the underground workings (referred to as the Mine Unit in the 2013 Mine Permit) and surface mine units that consisted of all activities at ground level needed for support of underground mining. These activities included:

- Hoisting of men, materials, and ore
- Ventilation and cooling of air for the underground workings
- Removal and treatment of mine water
- Disposal of waste rock
- Administrative, health and safety, and maintenance services
- Stockpiling and loading of ore for offsite milling

The location and identification of mine facilities are shown in Figure 1-2 and Figure 1-2b. Mine units are delineated primarily by function and secondary by location; there is some overlap in locations of the mine units. The mine units are described in the following sections:

- Underground Mine Unit (Section 2.4.1)
- Mine Dewatering and Mine Water Treatment Unit (Section 2.4.2)
- Service and Support Unit (Section 2.4.3)
- Low-Grade Ore Stockpile and Ore Pad (Section 2.4.4)
- Waste Rock Pile and Disposal Cell (Section 2.4.5)
- Storm Water Ponds (Section 2.4.6)
- County Road (Section 2.4.7)

### 2.4.1 Underground Mine Unit

The facilities in this category, collectively called the Underground Mine Unit, consist of below-surface facilities - the two shafts and associated underground workings. The underground mine workings, including all drifts, stopes, haulage ways, and other openings for ore extraction are shown on Figure II of the Environmental Site Assessment (RGR, 1994a). These underground workings follow the ore body at depths of 3,100 to 3,200 ft bgs. The shafts and conduits penetrate all the geologic units and aquifers described in Sections 2.2 and 2.3.

The Mt. Taylor Mine has two shafts: a production shaft (24-foot diameter) and a manway/ ventilation shaft (14-foot diameter). In addition, two 10 ¾ -inch inner diameter (I.D.) utility conduits (pipes) extend from the ground surface to the mine level. The conduits are steel casings/pipes, grouted in place. The conduits are 11.5 inches outer diameter (O.D.), cemented in place in 12.5-inch diameter boreholes through the entire length of 3,100 ft (north conduit) and 3,200 ft (south conduit). The annulus between the steel casing/pipe and the bore hole is cement grouted. The grout isolates the conduit from all aquifers except the Westwater at the mine level. As previously requested by MMD and approved in the Mine Permit, the entire length of each conduit will be grouted closed during closeout/closure.

Both shafts have slip-formed, cast-in-place concrete liners from collar level to mine level. The liner thickness increases with depth, from 1 ft at the sub-collar level to 3 ft at the mine level. The rock/concrete contact is pressure-grouted through the water-bearing sections from the Point Lookout aquifer to the shaft stations at mine level, isolating the shafts from the aquifers above mine level and the aquifers from each other.

The hydrologic isolation of the shafts and the mine water from the PLH aquifer is demonstrated by the difference in static water levels between the shafts and the Phase I dewatering wells that are completed in the PLH aquifer (Table 1-2). Water level data have been routinely measured at four Phase I wells since 2023. Potentiometric surface maps developed from that data (Figure 2-5)

indicate that the water level elevation of the PLH aquifer is approximately 6,830 ft above mean sea level (ft amsl) at the 14-ft manway shaft and approximately 6,780 ft amsl at the 24-ft production shaft.

The field-measured water level elevation within the production shaft is approximately 6,567 ft amsl, or about 263 ft lower than the projected potentiometric water level elevation in the PLH.

Dewatering operations ended around 1990. Water levels within the Point Lookout wells and within the production shaft have stabilized following recovery since dewatering ended 35 years ago. The water level being over 200 ft lower in the production shaft than the Point Lookout aquifer indicates that there is no discernible hydrologic connection between the mine water (Morrison/ Recapture/Westwater) and the PLH. If a connection existed between the shafts and the PLH aquifer, water levels in the mine shafts would be similar to those in the PLH. The isolation of mine water from the PLH is also evident from the differences in water quality between the mine water (Table 2-1) sampled from the production shaft and the PLH water sampled in the dewatering wells (Table 2-2).

### 2.4.2 Mine Dewatering Wells and Mine Water Treatment Unit

#### 2.4.2.1 Mine Dewatering Wells

The mine facilities included deep dewatering wells for removing water from the mine, a MWTU, and a Treated Water Discharge Pipeline. During initial mine operations, water was pumped from up to 22 deep wells to dewater the mine. These wells are located concentrically around the shafts, as shown in Figure 1-4 and listed in Table 2-3.

When the mine was operating, these facilities were used to pump, treat, and discharge up to 7,200,000 gallons per day. However, during mine standby and the more recent active status period (2018-2019), no mine water was discharged, and these facilities were not in operation.

#### 2.4.2.2 Mine Water Treatment Unit

The MWTU is regulated under DP-61, which was originally approved on July 20, 1979, and subsequently renewed every five years hence. DP-61 is in the process of timely renewal concurrently with RGR's application for renewal of the Mine Permit.

The MWTU covers 28 acres of land surface within the Mine Permit boundary. The mine water treatment unit included the water treatment equipment and buildings (Ion Exchange plant, flocculant treatment, and barium chloride treatment facilities), as well as the ponds, which had an original combined capacity of approximately 62 acre-feet (RGR, 2013b).

In the 1970's and 1980's, when the mine was operating, the mine water was treated in the MWTU to remove low concentrations of uranium and radium so that the treated water met human health standards (NMAC, 2018a). Treatment consisted of sediment settlement assisted by flocculation and precipitation of radium using barium chloride. An ion exchange (IX) circuit for removal of uranium was constructed but never placed into full operation because the uranium concentrations

of the mine water were below the groundwater standard (5 mg/L) in effect at that time. The IX circuit was run only in an initial test mode; it was not subsequently used for uranium removal.

Mine water was first treated with flocculant before being released into Pond #1. Mine water then flowed from Pond #1 through Ponds #2 and #3, where settling of suspended solids occurred. The settled mine water then flowed from Pond #3, through the barium chloride mixing facility, and into Pond #8. From Pond #8, the treated water flowed into Pond #4, then into Pond #5. Through the addition of barium chloride, barium precipitation was induced (barium-radium-sulfate co-precipitation) as the mine water flowed through these three ponds. After barium precipitation in Pond #5, the treated water flowed into Ponds #6 and #7 before release to the discharge pipeline.

From Pond #7, treated water was pumped through a 4.3 mile long, 24-inch diameter discharge pipeline and discharged to San Lucas Canyon (Figure 1-3) under authority of NPDES Permit No. NM0028100. The pipe was constructed above-ground and consisted of 1/4- to 3/8-inch thickness steel sections, welded in the field.

The MWTU was upgraded during the mine reactivation period (2018-2019), after the Mine Permit was revised to active status. During this time, MWTU Ponds #2 and #3 were enlarged in 2019 and 2018, respectively; existing hydraulic structures were refurbished, new concrete spillways were constructed at the inlets, and double-membrane high-density polyurethane (HDPE) liner systems were installed according to DP-61. Both ponds were enlarged for increased storage capacities (Table 2-4). Excavated contaminated soils generated during the reshaping activities were placed in the disposal cell.

MWTU Pond #3 is being used to retain and evaporate contaminated water and fluids generated around the site, including groundwater from abatement activities, surface water runoff collected from containment structures, monitor well purge water generated from sampling, and wash water generated on site from equipment and materials decontamination. MWTU Pond #2 is not regularly in use; it serves as backup storage in case MWTU Pond #3 becomes filled to capacity. A shallow pool of clean water is maintained in MWTU Pond #2 to preserve and maintain the liner.

MWTU Ponds #2 and 3 will remain in place until groundwater abatement objectives have been achieved, and site decontamination activities are no longer required. These ponds were constructed as below-grade basins excavated into native rock and soil. When no longer needed, these two ponds will be reclaimed. The sediments contained on the liners will be removed and placed in the disposal cell. The hydraulic structures and liners will then be removed and placed in the disposal cell. The berms will be pushed in, and the ponds backfilled and regraded to meet final grading contours (Drawing Sheets CL 07A and CL 08). The pond areas will then be re-vegetated according to Appendix F.

MWTU Ponds #1, 4, 5, 6, 7, and 8 were excavated in 2019, during the reactivation phase, to remove contaminated sediments and soil, which were subsequently placed in the disposal cell. These ponds were not relined and never put into use during active status because RGR initiated closeout/closure activities before those ponds were re-constructed.

Demolition of the MWTU pond hydraulic structures, with the exceptions of Pond #2 and 3, were completed 2026.

Once the disposal cell expansion is approved, RGR will complete cleanup and reclamation of MWTU Ponds #1, 4, 5, 6, 7, and 8. After these six ponds are demonstrated to be clean, the berms will be pushed in, and the ponds backfilled. These six ponds will be regraded to meet final grading contours during closeout (Appendix A Drawing Sheets CL 07A and CL 08).

### 2.4.3 Service and Support Unit

The Service and Support Unit includes all surface facilities other than mine water treatment and mine waste rock disposal. The location and identification of these facilities are shown in Figure 1-2b and listed in Table 4-2.

Service facilities are those units at ground surface that supported the overall mine operation but do not provide direct support for underground operations. These units provided site access control, administrative services, personnel and sanitary services, warehousing and storage, maintenance and repair, water and power utilities. The facilities included the guard house, fire equipment building, service building, car (maintenance) shop, carpenter shop, electrical building, water treatment building, storage building, core storage building, water tanks, fuel storage tanks, fan shop, septic tank, leach field, and water wells for water supply to the mine.

Support facilities are those facilities at ground surface (above the shaft collars) that had a direct function in underground mining operations. These support facilities supplied air for ventilation; pumping water from the underground space; cooling and heating of underground air; and hoisting of personnel, materials, and ore to and from the underground mining levels. The mine support facilities included the compressor building, chiller building, cooling towers, chiller pump building, shaft heating buildings, hoist house, headframes, and exhaust fan structure.

An electrical substation is located on the north side of the service and support facilities area. This substation is owned by the Continental Divide Electric Cooperative and Public Service of New Mexico and is not subject to regulation under the Mine Permit. However, because the substation has some contamination from fugitive dust, it is an affected area and will be cleaned up during closeout/closure.

### 2.4.4 Low-Grade Ore Stockpile and Ore Pad

The ore stockpile covered 6.8 acres and contained approximately 60,000 tons of low-grade ore. The ore stockpile has been removed, and the ore has been trucked to the White Mesa uranium mill in Utah.

In the previous version of the CCP, a new 10-acre ore pad was to be constructed with a liner, truck wash, and runoff collection system as described in RGR, 2013b. These improvements were never constructed and are no longer proposed at the site.

As part of closeout, the surface soils currently in the ore pad will be removed to eliminate any soil contamination from the ore stockpile. Contaminated soils in the ore pad will be placed in the disposal cell. This is described further in the Earthwork Section 4.4.3.

### 2.4.5 Waste Rock Pile and Disposal Cell

This mine unit consists of the original Waste Rock Pile (WRP) and the expanded disposal cell within and adjacent to the original WRP footprint. Together, these features serve as the permanent repository for radiologically contaminated materials, diesel-impacted soils, site debris, and other affected materials generated from the Mt. Taylor Mine and its affected areas.

The original WRP is comprised of waste material generated from previous mining and development activities, including approximately 698,000 tons of waste rock extracted and managed during the 1986 to 1990 production period alone. The disposal cell is a distinctly separate engineered structure constructed above and adjacent to the WRP and intended to contain newly generated site waste. Its low-permeability liner and engineered 52-inch store-and-release cover system, consisting of a 12-inch rock mulch surface, a 28-inch on-site soil buffer, and a 12-inch compacted clay radon barrier, are designed to reduce infiltration, attenuate radon, and minimize contaminant leaching and mobilization.

The existing WRP was reshaped during the mine reactivation period (2018-2019) and occupies 13 acres in the southwest corner of the surface facility area. Upon resuming mining operations, waste rock was to be placed on this pile until it reached the maximum build-out configuration. The WRP contains waste rock (rock with uranium content below economic value), excavated during mine development and production, from non-ore-bearing formations or below-ore-grade rock in the mine.

The mound of material previously located at the southwest corner before 2018 was shaft muck excavated from strata above mine level, meaning its radionuclide content was essentially at background levels. The shaft muck pile was reshaped into the south sloping berm of the current WRP and disposal cell during the 2018 reconstruction period.

The WRP also contains a variety of non-rock waste from the mine such as rock bolts, timbers, ventilation bags, pipes, and other mine-related debris. These materials occur randomly throughout the pile. Waste rock removed from underground mines typically includes non-rock materials that are hoisted alongside the rock and remain mixed when placed in the WRP. At the Mt. Taylor Mine, this mixture has been in place for up to 38 years with no visible evidence of settlement.

Non-rock waste (site debris and scrap materials) generated during closeout/closure will be placed in the disposal cell under controlled procedures to minimize future settlement. Structural materials and dismantled equipment will be cut, crushed, or reduced to manageable dimensions, and oversized components will be placed so surrounding earthen material can be compacted against them to eliminate bridging and unsupported voids. Hollow items such as pipes, conduits, tanks, and vessels will be filled with clean earthen material or flowable fill. Disposal cell fill will be placed in controlled loose lifts not exceeding 12 inches and compacted to least 90 percent of maximum dry density, with representative waste samples tested for consolidation and swell so

final grading can include sufficient camber. The cell will also accommodate approximately 7,400 cubic yards of non-hazardous diesel-impacted soils from the North Controlled Area, placed in a documented and controlled manner within the lined and covered repository.

### 2.4.6 Storm Water Ponds

Two runoff retention ponds, the north storm water pond (NSWP) and the south storm water pond (SSWP), capture and retain runoff from areas of the mine surface that contain ore or waste rock (Figure 1-2). The NSWP is also referred to as the ore pad runoff retention pond.

The NSWP (0.9 acres), located between the ore stockpile pad area and the mine water treatment area, retains runoff from the ore pad and holds it until it evaporates. The NSWP will be remediated as part of closeout, once the disposal cell expansion is approved and after the ore pad is removed.

The SSWP was reconstructed in 2018 to its current size of 2.67 acres (Kuhn, 2019) increasing the capacity sufficiently to hold the runoff of two 100-year storm events. The SSWP retains storm water from the existing WRP and the service and support facilities and will remain as part of PMLU after closeout/closure to retain and evaporate site runoff.

During reactivation (2018), the sediments and contaminated soils in the SSWP were excavated and placed in the disposal cell. Once cleaned, a 2-ft thick clay liner was installed over the floor and sides (Kuhn, 2019). Subsequent runoff from the mine facility has introduced new contaminated sediment onto the pond floor, as anticipated. Once closeout/closure is completed, these newly deposited contaminated sediments will be excavated and placed in the disposal cell.

Along with reconstruction of the SSWP during mine reactivation (2018-2019), the mine facility runoff that formerly flowed to MWTU Pond #2 was rerouted via reconstructed and new storm water pipe system to the SSWP. At this time, all mine facility storm water runoff has been diverted to the SSWP, including the catchment of storm water runoff from the disposal cell. Upon closeout/closure, this runoff will continue to be diverted to the south storm water pond.

All contaminated soil from the cleanup of both ponds will be placed in the disposal cell.

### 2.4.7 County Road

County Road 334 (County Road), also known as the Access Road, is a public gravel road and right-of-way, totaling approximately 4.7 acres, maintained for the State of New Mexico by Cibola County, that provides access to the west edge of the Cibola National Forest; it is not part of the Mine Permit area, and not subject to closeout. However, contaminated soil along and or on the County Road corridor will be removed and the road surface restored during closeout/closure.

# 3.0 POST MINING LAND USE

## 3.1 Factors in Selection of Post-Mining Land Use

In selecting post-mining land uses (PMLUs) for the permit area, RGR considered many factors. These included:

- Technical feasibility
- Economics
- Land ownership
- Current and possible future surrounding land uses
- Public interests
- Site resources and ecosystems
- Environmental impacts and standards

*Technical feasibility* - No PMLUs were considered for which necessary technology does not presently exist.

*Economics* - This factor consists of two parts, economic feasibility and economic compatibility. A PMLU should have net positive economic returns (returns at least equal to costs). The net returns can be in the form of revenues, cost savings, or any combination of these. The PMLU should work positively within the local economy, either by improving it or helping to sustain it.

*Land Ownership* - RGR controls, either through direct ownership or through leases with landowners, the permit-area surface listed in the Permit Application. RGR owns the surface land in the E-1/2, Section 24, T13N, R8W, containing the mine facilities, apart from a wedge-shaped portion of land around the SSWP, which is leased by RGR.

*Current and possible future surrounding land* - The surrounding lands have been used for livestock grazing and small-scale logging for several generations, and these uses are expected to continue in the foreseeable future. The Cibola National Forest to the east provides several recreational, commercial, and cultural uses available to the public. The selected PMLUs should be consistent and compatible with surrounding land uses but need not be the same uses.

*Public interests* - The San Mateo community has a strong cultural heritage and places great value on its rural, independent lifestyle. PMLUs that would require substantial new infrastructure or impose demographic changes were avoided to reduce the chance for negative impacts to the community.

*Site resources and ecosystems* - RGR examined the resources of the site other than the uranium ore, especially those already disturbed by mining, to identify which ones have potential for productive use after mining. Site resources include both natural and man-made attributes of the

site. Water removed from the mine and some mine surface facilities are resources that have potential use after mining operations. Reclamation should restore the pre-mining ecosystem to the extent consistent with the PMLU(s).

*Environmental impacts and standards* - Potential PMLUs should limit land disturbance or, preferably, contribute to mitigation of mining disturbances. Each PMLU must be able to meet standards for air and water protection established by NMED and federal agencies as applicable.

## 3.2 Potential Post-Mining Land Uses

Using the factors described above, RGR identified the following potential PMLUs:

- Livestock grazing
- Wildlife habitat
- Commercial, government, or light industrial facilities

*Livestock grazing* as a PMLU is consistent with surrounding and historical land uses and local public interest. It is also consistent with the wishes of those land surface owners who have expressed a preference. This use will be facilitated through covering of the WRP and mine water treatment ponds, final grading of disturbed surfaces, and revegetation. This PMLU could coexist with or next to the other potential PMLUs and would restore the pre-mining ecosystem.

*Wildlife habitat* is consistent with surrounding lands uses and community values. It is readily implemented with the same measures used for establishing livestock grazing.

*Commercial, government, or light industrial facilities* would make use of some existing mine buildings and infrastructure, all in usable condition, for offices, services, manufacturing, storage, or wholesale/retail sales, providing a center for employment in the San Mateo area. This use is compatible with a municipal/industrial water supply or livestock grazing PMLU but is generally not compatible with wildlife habitat. The mine surface facilities include office, warehouse, and maintenance facilities that could be used by other mining operations in the area or by land management agencies such as the Bureau of Land Management and the U.S. Forest Service. Although located away from main transportation routes and in a sparsely populated area, the mine facilities could also support light industrial uses.

## 3.3 Selected Post-Mining Land Uses

For the purposes of this CCP, RGR has selected grazing and light industrial as the primary PMLU and the basis of the cost estimate for financial assurance. RGR intends to utilize the selected buildings (retained for PMLU, Table 4-2 and Figure 1-2b) for its continued business operations in New Mexico and focus on maintaining a continued presence at the Mt Taylor facility. The buildings and facilities will provide storage and maintenance of its equipment, as well as office space for RGR's site personnel and current and future business opportunities, including light industrial, commercial, or government uses. The equipment will be used to maintain the PMLU facilities (water wells, grazing endeavors, other business potential).

### 3.3.1 Grazing

As stated in the Mine Permit Application (RGR, 2022a), prior to the development of the mine, the site was used for grazing by generations of the same families. Specifically, the surface owners have grazed livestock on, or expressed this preference for, the following areas:

- Portion of NE 1/4, Section 24 - This is the northerly portion of the mine surface area, containing the Mine Water Treatment Unit as well as the county road right-of-way. RGR is the surface owner of this tract. This land has been grazed historically so the non-excluded parts of this surface will be returned to grazing as the PMLU.

- Portion of SE 1/4, Section 24 - This is the southerly portion of the mine surface area as well as undisturbed land south of the mine facilities. It contains most of the surface support and mine support facilities and the WRP. RGR is the surface owner of all but a wedged-shaped portion of this tract (see bullet point below).

- Northwest Portion of SE 1/4, Section 24 - This triangle of land, about six acres owned by others, is the surface presently occupied by part of the WRP and the adjacent storm water retention pond. A land swap agreement to transfer title of this land to RGR is anticipated. This triangle of land would be included subsequently with the rest of the SE 1/4 of Section 24. The SSWP will be retained as a stock tank, and the remainder of the area will be converted to grazing except for the WRP, which will be fenced to exclude grazing.

### 3.3.2 Light Industrial, Commercial or Government Facilities

The existing service and support facilities are multiple-use buildings that support office, warehouse, and maintenance/repair activities. Some buildings and facilities will be left in place to support agricultural operations and future light industrial, commercial, or government uses. As the landowner, RGR desires that the facilities designated in Table 4-2 and shown on Figure 1-2b, together with the water supply wells shown on Figure 1-4, remain in place for these post-mining land uses.

### 3.3.3 Facilities Retained for PMLU

The following facilities will remain in place for PMLU:

- Guard House (Security Building)
- Core Storage Building
- Fan Shop
- Capacitor Building
- Ion Exchange Plant (for warehouse and equipment storage)
- Septic System (septic tank, leach field, and piping)

- Site water use wells: DW-1, DW-2A, DW-6, DW-7, and DW-8
- Monitoring wells: DW-1 and DW-14 (site water use backup wells)
- Water Tank
- Service Building
- Electrical Building
- Hoist House and Rocky's Shop (for warehouse and equipment storage)
- Access/Utility Tunnels necessary for the PMLU facilities
- South Storm Water Pond
- Storm Drainage System
- MWTU Ponds #2 and #3 (until groundwater abatement per DP-61 is completed)

These facilities are listed on Table 4-2 and shown on Figure 1-2b and Figure 1-4.

### 3.3.4 Radiological Levels for PMLU

Preliminary surveys performed in the habitable buildings designated for the PMLU indicate that radiological surface contamination does not exceed the gross alpha surface contamination limit of 5,000 dpm/100 cm² specified in the MMD-approved March 2021 Site Radiation Protection Program Manual (Table 3-1a). A final radiological characterization survey will be conducted prior to completion of mine closeout/closure to determine whether radiological contamination associated with closeout/closure activities has affected these facilities. Areas with radiological surface contamination exceeding 5,000 dpm/100 cm² gross alpha will be decontaminated, as necessary, to meet the applicable release criterion. The selected criterion of 5,000 dpm/100 cm² gross alpha is consistent with NRC Regulatory Guide 1.86 and is more conservative than the surface contamination level calculated to correspond to a 100 mrem/yr dose limit. No Waiver from Self-Sustaining Ecosystem or Post-Mining Land Use

RGR is not seeking a waiver from the regulatory requirements to establish a self-sustaining ecosystem or post-mining land use under 19.10.5.506C and 507B NMAC. RGR proposes livestock grazing as the primary PMLU for the broader permitted area, with wildlife habitat as a natural, compatible, and concurrent use. Once native vegetation is successfully re-established on reclaimed portions of the site not used for other purposes, grazing is expected to be sustainable and consistent with the historical and generational land use of the San Mateo area. The WRP and expanded disposal cell area will be fenced and permanently restricted from livestock grazing to protect the engineered cover system, including the rock mulch erosion layer, store-and-release soil cover, and shallow-rooted native grass community needed for long-term evapotranspiration performance.

Light industrial, commercial or government use of the service and support structures to be left in place, are additional PMLUs that will provide valuable infrastructure for sustainable economic opportunities for the San Mateo community and for RGR's continued business endeavors in New Mexico.

# 4.0 DESCRIPTION OF CLOSEOUT/CLOSURE ACTIVITIES

RGR's mine reactivation program, initiated in January 2018 and suspended in December 2019, was structured in four sequential phases:

- Phase 1 – Environmental Upgrades
- Phase 2 – Water Treatment Facilities Upgrades
- Phase 3 - Dewatering and Water Treatment Reactivation
- Phase 4 – Underground Facilities Reactivation

The scope of Phase 1 was focused on environmental clean-up and environmental upgrades identified in the Revision 13-2 of the Mine Permit (RGR, 2013b) and set as priorities in the Implementation Plan of DP-61.

Phase 1, initiated in 2018, was planned to include activities that were equally necessary for both reactivation and closeout/closure. Phase 1 was substantially completed by December 2019 and included (Kuhn, 2019):

1. Reshaping and flattening the west and northwest slopes of the WRP to 5H:1V grades.
2. Constructing the south and west berms of the disposal cell.
3. Constructing the disposal cell clay liner.
4. Excavating radiologically contaminated sediments and soils from all MWTU pond basins and placing material in the disposal cell.
5. Reshaping of MWTU Ponds #2 and #3 and upgrading their associated hydraulic control structures.
6. Reshaping and lining the SSWP and installing hydraulic control structures.
7. Installing double HDPE liner systems in MWTU Ponds #2 and #3.
8. Leak testing and commissioning of MWTU Ponds #2.
9. Upgrading and extending the surface water drainage system.
10. Constructing the new septic system.
11. Installing the North Force Main.
12. Began removing ore from the low-grade ore stockpile to an off-site licensed facility at MMD and NMED direction.

The Phase 1 work started in January 2018 with the preparation of construction bid documents. Earthwork began in May 2018, focused on reshaping the WRP and SSWP, reconstruction of the stormwater drain system, initial construction of the disposal cell and reconstruction of MWTU Pond #3. Phase 1 construction work was substantially completed by the end of December 2019 and was addressed in supplemental reports of closeout/closure construction in 2020 and later.

Removal of the ore pad was the only Phase I activity not initiated before the end of 2019. This activity could not begin until all the low-grade ore on the pad had been removed. Ore pad removal was completed in April 2022. Removal of the ore pad material is pending approval of the disposal cell expansion.

After RGR made its decision to begin the closeout/closure process of the mine, work related solely to mine reactivation in Phases 2, 3 and 4 ceased. RGR continues to conduct closeout/closure activities under its active status permit. Many activities, such as earth moving and facility removal, are suspended until approval is granted to expand the disposal cell. Expansion of the disposal cell is necessary as the existing and approved 13-acre disposal cell has been filled to near-capacity by the volume of contaminated sediments and soils excavated from the MWTU ponds (Ponds 1 through 8) during Phase I.

The following sections describe the closeout/closure practices (Section 4.1), activities completed by September 2026 (Section 4.2) and activities remaining to be completed (Section 4.3).

## 4.1 Closeout/Closure Practices

For Phase 1 and subsequent closeout/closure activities, Best Management Practices (BMP) were followed and will be followed, including "Best Practice in Environmental Management of Uranium Mining," IAEA Nuclear Energy Series NF-T-1.2. (IAEA, 2010), and Federal Highway Administration (FHWA) Best Management Practices for Erosion and Sediment Control FHWA-SLP-94-005 (Roberts, 1995). Technical specifications for some measures, as appropriate and as previously provided in the CCP, are contained in Appendix C. Future technical specifications of closeout/closure measures will be provided as part of submitted work plans or design sets. Select closeout/closure measures are illustrated in the drawing sheets contained within Appendix A Drawing Sheets CL 05, CL06, CL 07A, CL 07B, CL 08 and CL 14.

All contractors using heavy equipment, trucks, and other materials involving fuel, lubricant, solvents or capable of collecting and transporting solid contaminants will be refueled, serviced, washed, and parked in a specified area. This area will be located by the contractor and approved by RGR. The area will include a temporary wash facility with a temporary liner and water collection system. Alternatively, a temporary decontamination area will be set at the concrete wash bay adjacent to the production shaft, unless and until it is scheduled for removal under closeout/closure. Wash water will preferentially be transported to MWTU Pond 3 and evaporated or evaporated at the temporary decontamination site. Residues from evaporated water will be removed for disposal, either temporarily stored for placement in the disposal cell or offsite in a licensed facility.

At the time of this submittal, small quantities of solvents and lubricants from the maintenance shops may remain on site at the time of closeout/closure. The products being used and expected to be in use throughout that time are listed in Table 4-1.

Radiation levels in the facilities that will be retained for PMLU do not exceed the NRC Regulatory Guide 1.86 criteria for unrestricted release and use. A final radiological characterization survey of these facilities will be conducted to ensure release criteria are met (see Section 3.3.4).

## 4.2 Closeout/Closure Activities Completed

Since early 2018, RGR has completed numerous closeout/closure activities, including those specific to Phase 1, in accordance with the Mine Permit. These activities include, but are not limited to, the dismantling of numerous service and support facilities deemed non-essential for PMLU (Section 4.2.1), addressing non-essential concrete foundations (Section 4.2.2), removal of other facilities (Section 4.2.3), and the regrading of the WRP (Section 4.2.4).

The following Phase I reactivation tasks have been completed during the period of Mine Permit No. CI002RE, Rev. 13-2 (after 12/29/2017):

1. Reshaping of the WRP
2. Construction of the disposal cell liner and south, west and north-west berms
3. Excavation of contaminated sediments and soils within the eight MWTU ponds.
4. Construction and commissioning of MWTU Ponds 3 and 2
5. Filling of the existing 11.5-acre disposal cell to near-capacity
6. Covering the filled disposal cell with 24 inches of compacted clay and 12 to 18 inches of loam soil
7. Re-constructing the SSWP and septic system
8. Upgrading the surface water drainage system
9. Removal of the low-grade ore stockpile

Table 4-2 lists the status of each mine facility and its disposition at the time of this report.

### 4.2.1 Removal of Service and Support Facility Units

At the time of this report, the following service and support facilities have been dismantled at the mine.

1. Compressor Building
2. York Chiller Building

3. Chiller Pump Building
4. Chlorine Building
5. Shaft Heating Buildings (2)
6. Glycol Heat Exchanger
7. Cooling Towers
8. Fire Equipment Building
9. Carpenter Shop
10. Water Treatment Building
11. Storage Buildings
12. Flocculant Treatment Building
13. Barium Chloride Treatment Facility
14. Portable Building
15. Fuel Pump House
16. Fuel Storage Tanks
17. Mine Ventilation Structure (fan and base)
18. Ore Car Rails
19. MWTU Pump House and Motor Control Center
20. Production Shaft Headframe
21. Manway/Ventilation Shaft Headframe
22. Car (Maintenance) Shop
23. Emergency Hoist House
24. Treated Water Discharge Pipeline
25. Chiller Building Electrical Room
26. Trailer House

Table 4-2 lists the status of these and other mine structures, as well as the facilities that will be retained for support of post-mining land use identified in Section 3.3.3.

The dismantled building materials have been sheared into manageable pieces and either scanned and transported offsite, staged for the disposal cell, or are waiting for scanning to identify the final disposal location. This will be determined through radiological scanning to evaluate whether the materials meet the acceptance criteria for offsite disposal, thereby minimizing the volume of material requiring disposal in the disposal cell

Once RGR completes the characterization and segregation of the materials qualified for unrestricted release, the clean material will be staged in the parking lot north of the guard house until they can be recycled.

The remaining materials intended for the disposal cell will be moved to one of three NMED-approved staging areas on the site (Figure 4-2). Waste materials stored within the three proposed staging areas are temporary. RGR intends to relocate all staged waste materials to the expanded disposal cell following plan approval by MMD and NMED.

The locations of the three staging areas and the surrounding stormwater drainage patterns are reflected in Figure 4-2. While the staging areas are open to direct precipitation, they are protected from surface water run-on and run-off through the following measures:

- Siting: The staging areas have been intentionally placed outside of concentrated surface water flows and within footprints previously approved by NMED (2024).

- Run-off Controls: Stormwater run-off from these areas is fully managed by the comprehensive engineering upgrades completed under the approved DP-61.

- Permit Compliance: These DP-61 upgrades were specifically designed and constructed to enhance NPDES compliance. They provide run-off controls and increased surface water retention capacity within the permit area. These controls are engineered to remain effective across all phases: active operating status, post-mining land use, and the long-term, post-closeout period.

These three areas were also selected based on the following operational and environmental criteria:

- Spatial Efficiency: The staging areas are strategically located outside the immediate footprint of the proposed disposal cell. This separation avoids operational interference, ensures safe equipment clearance, and facilitates uninterrupted construction of the disposal cell upon approval.

- Minimizing New Surface Disturbance: The staging areas utilize existing, historically disturbed footprints from previous mining operations. By confining temporary storage to these already developed operational areas, RGR avoids impacting undisturbed native ground surfaces or undisturbed topsoil resources.

### 4.2.2 Concrete Foundations

Concrete foundations (including floor slabs) of the facilities will be either:

- Left in place and rubblized, then covered with clean soil; or

- Left in place intact.

- Rubblized and then placed in the disposal cell.

If no other purpose can be found, the rubblized concrete will be placed in the expanded disposal cell. All concrete left in place will be covered with two feet of soil.

Prior to removal of facilities and buildings, and breakage of the associated concrete foundations, radiological surveys of the structures will be conducted to determine whether the materials meet free-release criteria. Only those concrete foundations meeting the release criteria of the appropriate NRC guidance, as demonstrated via the radiological survey results, will be buried in place. Those that fail to meet release criteria will be buried in the disposal cell along with other contaminated materials. RGR will make reasonable efforts to reduce the amount of materials to be placed in the disposal cell through characterization studies. Materials found not to be radiologically contaminated will be separated and buried as clean fill or released from the site for proper disposal or recycling.

Table 4-2 provides a list of the disposition of the facilities and foundations. Except for the Electrical Building (preserved for PMLU), all facilities on the Compressor bench are to be removed in preparation for remediation of potentially diesel-contaminated soils existing beneath portions of the Compressor bench.

The foundations for the fire equipment building, emergency hoist house, glycol heat exchanger, and storage building are to remain intact for use as material storage areas for PMLU. The radiological surveys for these facilities demonstrated that the release criteria were met (Table 3-1c).

The concrete foundations around the manway shaft and production shaft will not be broken, so as to provide protection and confinement for the shaft plugs (when constructed). These foundations will be covered with two feet of clean soil once construction around the shaft is completed. In addition to providing a growth medium for revegetation, the soil cover will also minimize the chances of surface stormwater from entering the shafts.

The following foundations have been rubblized (Table 4-2):

a. Water Treatment and Boiler Building (#09 on Table 4-2): foundation also removed
b. Compressor Building (#10 on Table 4-2): foundation staged
c. Portable Building (#12 on Table 4-2): foundation also removed
d. Fuel Pump House (#13 on Table 4-2): foundation also removed
e. Carpenter Shop (#14 on Table 4-2): foundation also removed
f. Fuel Storage Tanks (#15 on Table 4-2): foundation staged
g. York Chiller Building (#17 on Table 4-2): cover pending
h. Car (Maintenance) Shop (#23 on Table 4-2): foundation also removed
i. Chiller Pump Building (#25 on Table 4-2): cover pending
j. Barium Chloride Treatment Facility (#31 on Table 4-2): cover pending
k. Flocculant Treatment Facility (#34 on Table 4-2): foundation also removed

l. Mine Water Treatment Pump House (#36 on Table 4-2): foundation also removed

m. Chiller Building Electrical Room (#40 on Table 4-2): cover pending

The foundations that remain and their disposition (Table 4-2) include:

a. Manway Shaft Headframe (#01A on Table 4-2): removed to ground surface, then remain intact for protection of shaft plug

b. Production Shaft Headframe (#02A on Table 4-2): removed to ground surface, then remain intact for protection of shaft plug

c. Shaft Heating Buildings (2) (#04A on Table 4-2): retain as part of shaft plug

d. Storage Building (#04B on Table 4-2): leave intact for PMLU

e. Emergency Hoist House (#04C on Table 4-2): leave intact for PMLU

f. Glycol Heat Exchanger (#05 on Table 4-2): leave intact for PMLU

g. Fire Equipment Building (#19 on Table 4-2): leave intact for PMLU

h. Cooling Towers (#26 on Table 4-2): foundation to be rubblized

i. Chlorine Building (#27 on Table 4-2): foundation to be rubblized

### 4.2.3 Removal of Other Facilities

The removal status of other facilities is:

a. Process Water Piping: estimated at 20% dismantled, temporarily staged for placement in expanded disposal cell

b. Mine Rails: removed, temporarily staged for placement in expanded disposal cell

c. MWTU Pond Hydraulic Structures: demolition was completed in 2026 for all ponds except for the MWTU Ponds #2 and #3 concrete overflow weirs, debris temporarily staged for placement in expanded disposal cell

d. Low-grade Ore Stockpile: removal completed, transported to White Mesa Mill

e. Discharge Pipeline and Structures: 100% dismantled, either recycled offsite after clearance or temporarily staged for placement in expanded disposal cell

The status of closeout/closure activities of facilities is summarized in Table 4-2. That table summarizes the disposition of mine facilities, including those already decommissioned or removed and those still to be either retained for post-mining land use or removed as part of closure activities.

### 4.2.4 Waste Rock Pile and Disposal Cell Status

The initial activity in Phase 1 construction involved re-shaping of the WRP, followed by construction of the disposal cell within the 11.5-acre WRP footprint approved under Revision 13-2

of the Mine Permit (RGR, 2013b). The integrated WRP and disposal cell are the permanent repository for radiologically contaminated materials generated on site that exceed applicable unrestricted release criteria. By December 2019, the disposal cell was filled to near-capacity after the MWTU ponds were remediated during the reactivation stage of the active status permit. Filling the disposal cell to near-capacity was a result of RGR's efforts to comply with the permit and remove all soils exceeding the accepted soil cleanup standard of 6.8 pCi/g Ra-226 (1.8 pCi/g background plus the 5 pCi/g regulatory limit). At that time, RGR recognized it could not proceed with earthwork remediation efforts unless the disposal cell was expanded. RGR continued to fill any available capacity of the disposal cell with contaminated materials throughout 2020 as it awaited decisions by MMD and NMED on expanding the disposal cell. As-built drawings for this phase are provided in Appendix J.

RGR submitted a permit modification request (MOD 20-1) in May 2020 to MMD (RGR, 2020), to alter the PMLU list of retained buildings, to expand the disposal cell from 11.5 to 25 acres, and to alter the closeout/closure schedule. MMD initially indicated a simple permit modification was appropriate under its definitions, however, NMED informed RGR that a formal modification of Discharge Permit DP-61 (as defined by NMED rules) would be required (NMED, 2021). As of the date of this CCP submittal, regulatory approval of the disposal cell expansion is pending. Because of the need for approval to expand the disposal cell, RGR has focused its closeout/closure efforts on removing facilities rather than continuing with earthwork remediation.

## 4.3 Closeout/Closure Activities Pending

At the time of this CCP submittal, the closeout/closure actions taken from 2018 through mid-2026 have accomplished many of the CCP goals. RGR continues to remove and encapsulate contaminants and facilitate the designated PMLU(s).

The large-scale site remediation will resume once regulatory approval of expansion of the disposal cell is approved as part of the DP-61 renewal and the Mine Permit revision.

Shaft closure, for the purpose of this CCP, and the information in Section 4.3.1 is unchanged. MMD has agreed to continued discussions and clarification which regulatory agency has shaft closure jurisdiction.

### 4.3.1 Shaft Plugging

Both the production shaft and the manway/ventilation shaft will be closed in the same manner, as approved in the current Mine Permit (RGR, 2013b) and detailed in Appendix A (Drawing Sheets CL 05 and CL 06) and Appendix C.3. In the approved Mine Permit design, the design utilized recycled steel from the headframes. However, a subsequent structural analysis revealed that this design did not provide an acceptable factor of safety against failure for the production shaft plug. A set of revised conceptual design drawings has been prepared by Critical View Engineering (Appendix G).

The updated design by Critical View Engineering is essentially the same concept of plug design as approved previously, namely a steel reinforced structural member. However, the construction materials are slightly different. The new concept is to utilize a steel (rebar) reinforced concrete

plug rather than steel I-beams encased in concrete. Structurally reinforced concrete is a proven and well-established structural member design, utilized in most new building construction around the world. The advantage of this revised concept is that the steel is encapsulated sufficiently to prevent corrosion, and the constructability of the structural member is more easily accomplished. The factor of safety is higher, and the structure is more efficient in shape and size.

Using the Technical Specifications in Appendix C.3, the entire closure plug will extend to a estimated depth of 62 ft in the production shaft and 40 ft in the manway shaft. Construction is anticipated to follow these procedures:

- Equipment and fittings within the shaft collar will be removed down to the sub-collar level.

- Once protruding steel and other obstructions have been removed below the sub-collar, a temporary work deck, supporting scaffolding, and concrete forms will be installed to facilitate construction of the reinforced concrete shaft plug

- The reinforced concrete shaft plug shall be constructed of reinforced concrete of appropriate design strength (Appendix A Drawing Sheets CL 05 and 06, Appendix G).

- The final shaft closure design will incorporate structural features to transfer plug loads into competent host rock rather than relying on the existing shaft lining for long-term support. These features may include rock keys or other engineered load-transfer mechanisms developed during final design. The final shaft closure design will be submitted for review and approval prior to construction.

- The structural plug will be constructed at the sub-collar level. The closure design does not include backfilling the shaft below the structural plug.

- Following curing of the reinforced concrete shaft plug, the shaft interval above the plug, including accessible connecting drifts and openings above the plug, will be backfilled with a controlled low-strength cementitious slurry consisting of soil, Portland cement, fly ash, and water. Mix proportions will be established during final design using laboratory testing of available materials.

- The remaining portion of the shaft collar will be capped with reinforced concrete and include a permanent survey/marker monument. The surface completion will accommodate and protect the two proposed shaft monitoring pipes while preventing surface runoff from entering the shaft. The final design will also include provisions for additional monitoring devices or sensors, if required.

Field evaluations are currently being conducted under the Site Investigation Plan (EA, 2025a) to address near-surface sub-collar seepage observed in the 14-foot diameter manway shaft. A targeted plan to seal this seepage will be developed based on these findings.

Infiltration or inflow of water from surface runoff will be prevented by the shaft plug and backfill in each shaft. The existing shaft liner and annular grout also provide a barrier to infiltration. Therefore, the proposed shaft closure measures will be protective of groundwater quality from both mine-level and surface sources of potential contamination.

A system of tunnels provides access to, and utility corridors for, the shafts and facilities (Figure 1-2b). The portions of the tunnels connecting directly to the shafts will be backfilled with slurried, weak, soil-cement (flowable fill) as part of shaft closure. The steel culvert running from the compressor bench to the car shop will also be closed with flowable fill.

### 4.3.2 Well and Conduit Plugging

#### 4.3.2.1 Conduits

Two vertical utility conduits, consisting of casings that extend from the ground surface down to the mine level, are scheduled for permanent plugging. Both conduits have an 11.5-inch outer diameter (O.D.) and are cemented in place within 12.5-inch diameter boreholes. The north conduit extends to a depth of 3,100 feet, while the south conduit extends to a depth of 3,200 feet.

All plugging activities will be conducted in strict accordance with NMAC 19.24.4. Prior to the commencement of any field activities, a comprehensive conduit plugging workplan—which will include the specific grout mix design and procedural methodology—will be prepared and submitted for regulatory approval.

#### 4.3.2.2 Dewatering/Depressurizing and Deep Aquifer Monitor Wells

As required under DP-61, two PLH aquifer wells, one THD aquifer well, and two WWC aquifer wells will be utilized for post-closure monitoring. Some of the existing dewatering wells may be suitable for that purpose, depending on well condition and the results of ongoing well rehabilitation efforts. The abandonment and potential replacement of certain wells may be required in some cases.

Regarding site water supply, at least one dewatering well completed in the PLH aquifer (DW-2A) is currently designated for domestic water supply and is utilized to provide water for site activities, such as well cleaning. This well, along with others designated for PMLU (e.g., DW-6, which is also equipped with a pump), will be retained to support mine site reclamation and will continue in that purpose throughout the CCP and post-closure monitoring.

Any dewatering well not used for site water supply or post-closure monitoring will be plugged and abandoned as part of site closure. Additionally, seven wells (designated as SM wells) used to observe drawdown in the mine area during active dewatering will also be plugged and abandoned (Figures 1-4 and 1-7). All wells that will be utilized for post-closure monitoring will be plugged and abandoned once post-closure monitoring is complete.

#### 4.3.2.3 Abatement Monitoring and Recovery Wells

There are 37 shallow alluvial and Upper Menefee wells in the groundwater-abatement monitoring program as of the time of this report (Figure 1-6 and Table 1-3). In the summer of 2026, 14 new

wells were installed to provide additional data on aquifer characteristics and to further delineate the extent of groundwater impacts from historical mining activities. Of these newly installed wells, 12 are designed for monitoring and two are intended for recovery (MW-1MR and MW-11AR). Notably, four of the new wells (MW-12, MW-13, MW-1MS, and MW-9S) were dry upon completion.

The new well installations are designed to provide critical data to address several key site objectives:

- Differentiate between the Menefee, alluvial, and shallow perched hydrostratigraphic units, and identify the variability and limitations of groundwater flow between them.
- Characterize aquifer properties and delineate the lateral and vertical extent of groundwater exceeding NMED water quality standards for uranium, selenium, and nitrate.
- Evaluate the hydraulic communication between the different hydrostratigraphic units.
- Identify areas of perched water and potential sources of groundwater recharge.

Additionally, the two newly constructed recovery wells (RW-1MR and RW-11AR) were intended to extract and remediate impacted groundwater near existing monitoring wells MW-1M and MW-11A. However, during extensive well development efforts, both wells were repeatedly pumped dry at low extraction rates of 1 to 1.5 gallons per minute. Additional evaluations are currently underway to determine the sustainable pumping rates of these wells and to assess their viability for long-term groundwater remediation.

The enhanced monitoring network reflects an improved understanding of site hydrogeology developed since implementation of the Stage 2 Abatement Plan (Metric, 2010). While the existing abatement program has reduced constituent concentrations in portions of the shallow groundwater system, additional investigations have shown that the hydrostratigraphic framework and the lateral and vertical extent of groundwater impacts were not fully defined. Consequently, additional monitoring and recovery wells are being installed to better characterize groundwater conditions and improve the effectiveness of future remediation efforts.

RGR has been addressing detected nitrate and uranium contamination under a NMED-approved Stage 2 Abatement Plan (S2AP) (Metric, 2010) since 2011. Once the abatement program objectives are achieved (to reduce constituent concentrations within the shallow groundwater system to levels that meet WQCC standards), these active abatement wells will be plugged and abandoned. Likewise, any future abatement wells that are installed will be plugged and abandoned once the wells' abatement program has ended.

Before plugging and abandoning is initiated for any wells, the contracted licensed water well driller will submit to the OSE a deep well plugging plan on OSE's Form WD-08 that will include:

- Sealant design with ratios and material specifications of seal components.

- Well construction details – borehole and casing diameters, screen types and intervals
- Depth to water
- Casing annulus seal description
- Plugging steps
- Documentation and reporting of well plugging

Plugging and abandonment will be conducted in accordance with the approved OSE well plugging plan and NMAC regulations (19.27.4 NMAC, 2017). The conduit and deep well plugging plan will be submitted for approval separately. Abatement wells and post-closure monitoring well plugging plans will also be submitted separately.

### 4.3.3 Surface Facilities Removal Pending

Surface facilities not needed for PMLUs described in Section 3.2, will be demolished. Table 4-2 lists all surface buildings, their sizes and their disposition at closeout/closure. Facilities remaining to be demolished include:

- Process water piping
- Remaining MWTU Ponds #2 and #3 hydraulic structures (concrete overflow weirs)
- Foundations (as detailed in Table 4-2)
- Sanitary Treatment Plant
- Ore Loading Pad and Wash Bay
- Shaft Sump Cleanout Bin
- Ore Pad Storm Water Retention Pond
- Plant and Refrigeration Water Pipelines
- CMP Utility Tunnel
- Ore Pad

Radiological characterization surveys have been and will be conducted to determine whether contamination exists at levels that exceed the NRC Regulatory Guide 1.86 criteria for unrestricted release.

Building demolition debris and other scrap materials will be managed based on these survey results:

- Unrestricted Release: Materials meeting the unrestricted release criteria, or those successfully decontaminated to meet them, may be removed from the site for salvage or recycling.
- Disposal Cell: Materials exceeding unrestricted release criteria, including contaminated demolition debris (e.g. scrap steel, pipe, and concrete), will be placed in the onsite disposal cell.

All pipes that are exposed and within three feet of the surface, except the potable water line in the utility tunnels, will be removed and buried in the disposal cell. Other pipes that are deeper than three feet will be either capped or plugged and left in place.

Demolition of facilities will include removal of concrete slabs or other foundations not needed for PMLU. Uncontaminated concrete slabs not retained for PMLU may be broken and covered by clean soil or removed for placement in the disposal cell.

Generally, MWTU ponds will be decommissioned during closeout/closure. However, MWTU Ponds 2 and 3 will remain in use until the groundwater abatement project is successfully completed. RGR envisions the need to keep these ponds for storing contaminated water for at least the first half of the 12-year period of responsibility. These two ponds are monitored for water quality and water levels quarterly, per requirements of DP-61, and will take additional time to remediate because of the steps involved:

- Evaporate remaining water.
- Remove and transfer contaminated sediments
- Remove pond liners.
- Demolish hydraulic controls structures and associated piping.
- Backfill the pond basins.

Contaminated pond sediments and soils in these pond areas will be removed and placed in the disposal cell. Contaminated demolition debris, including scrap steel, pipe and concrete, will be placed in the disposal cell. Clean debris may be removed from the site for salvage and recycling.

The buried drainage culvert from the storm drain along the county road (Figure 1.-2b), which diverts runoff away from the mine water treatment area, will not be removed. As part of the PMLU, it will continue to direct water to the SSWP.

## 4.4 Earthwork

Excavation of soils that require cleanup as part of the closeout/closure will begin after the disposal cell footprint is expanded. Cultural resource surveys, and clearances if required, will be performed on any land surface not previously surveyed that will be disturbed by closeout earthwork. In general, earthwork will involve short hauls by dozer to redistribute berm fills or mine waste rock and by scraper, excavator and trucks or grader for contaminated soil removal. Some loader

excavation and short truck hauling may be required, as well. Except for short pushes of up to 300 ft on pond berms and WRP slopes, the working grades are less than 5%.

Borrow Area A, located within the permit area and previously approved for use under the current Mine Permit, is no longer expected to provide the primary volume of clean soil needed for the expanded disposal cell. The 2025 borrow source investigation indicates that Borrow Areas A and B have been partially or fully excavated during previous construction activities and that remaining quantities are likely insufficient for the proposed expansion. RGR therefore intends to use clay deposits identified in Borrow Area C, within the permit area, as the preferred primary source for clean clayey soils needed for engineered caps, low-permeability layers, and clay liner components. Borrow Area B, west of the permit area on RGR land, may be retained only as a supplemental or alternate source if usable quantities remain. Borrow Area C is approximately 14 acres in size and is preferred because it is undisturbed and can provide a substantial volume of fine-grained, clay-rich material with favorable engineering properties.

In 2025, Engineering Analytics (EA) completed a borrow source investigation for Borrow Areas A, B, and C. The investigation included the excavation of 24 test pits excavated to depths of approximately 6 ft, including six in Area A, five in Area B, and 13 in Area C, as documented in the *Expanded Disposal Cell Design* report (Appendix K; EA, 2026c). The investigation concluded that Areas A and B have been partially or fully depleted by prior containment cell construction, while Borrow Area C contains undisturbed, fine-grained, clay-rich soils suitable for low-permeability cover, cap, and liner applications. Subsequent laboratory testing confirmed that Borrow Area C soils exhibit properties consistent with engineered cover requirements, including moisture content, Atterberg limits, percent passing No. 200 sieve, Standard Proctor compaction, soil water characteristic curve, flexible wall permeability, and consolidated undrained triaxial shear testing.

The proposed access to Borrow Area C will be provided via the existing access road that exits the MWTU area through the north gate, crosses over the Marquez Arroyo, and connects to a newly constructed gravel road, as shown in Figure 1-2. Reclamation of the access road and borrow area will include regrading the ground to minimize water ponding, scarifying the ground, and revegetating according to Appendix F.

Cut slope stabilization will focus on maintaining existing infrastructure while improving localized stability where needed. Cut slopes above the chiller bench will remain at their current slope to maintain existing wells and conduits at base of slope. A protective fence will be installed at the top of the wall. The slope below the chiller bench requires no additional work, because it is already stable and vegetated. The cut slope to the south of the hoist house will have additional fill placed at the toe and extended upward to the base of the existing wire fencing to improve stability.

Once the disposal cell expansion is approved, contaminated soil removal will proceed in a controlled sequence that supports radon attenuation, maintains cell stability, and separates materials by placement function. Soils from the NSWP and ore pad area will be removed first because these materials contain residual low-grade uranium ore from mine production. They will be placed toward the bottom of the disposal cell to minimize radon flux through the final cover.

Diesel-impacted soils from the 2019 release area will be placed next because they contain weathered hydrocarbons, no free-phase product, and compaction behavior compatible with engineered placement. Contaminated soils from the support area and other operational zones will then be placed above the petroleum-impacted soils, followed by remaining contaminated soils from the MWTU area and affected lands outside the mine site. A secondary disposal cell will be built abutting the proposed main cell to contain materials from MWTU Ponds 2 and 3, the SSWP, and miscellaneous contaminated sediments. Table 4-4 lists the estimated quantities and locations of these materials prior to excavation.

Site regrading after soil cleanup will be completed using soils from previously disturbed areas to the extent practicable. Sufficient native fill volumes are calculated to be available from the design cut quantities on site (Table 4-3). For engineered caps, low-permeability layers, clay liner components, or other clean soil needs associated with the expanded disposal cell, Borrow Area C will be used as the preferred primary source. Borrow Area B may be retained as a supplemental or alternate source, only if usable quantities remain. These soils consist of sandy clay, clayey sand and clay with Unified Soil Classification of SC and CL as determined by test pits and laboratory testing and meet the engineering requirements for reclamation fills and engineered cover applications. Table 4-3 lists the estimated clean soil requirements, source areas, and overall earthwork balance.

The United States Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS) web site (NRCS, 2026) indicates that site soils will naturally support western wheat grass, vine mesquite, alkali sacaton, and four-wing saltbush. Site soils consist primarily of low-to-moderate plasticity clays and sandy clays, with localized alluvial sands, gravel, and cobbles in arroyo deposits. Contaminated soils will not be used for closeout/closure covers, reclamation fill, or backfill outside the engineered disposal cell.

### 4.4.1 Existing Waste Rock Pile

Starting in 2018, RGR reclaimed the WRP to protect it against erosion. In the initial step of this reclamation, RGR reshaped the existing WRP to enhance long-term structural stability. The north, west and south slopes were flattened to 5H:1V, as represented in the lower slopes shown in the disposal cell as-built drawings (Appendix J), and then covered with 2 ft of compacted clay. The clay was sourced from Borrow Areas A and B, which were partially or fully depleted during prior containment cell construction, and from the clean shaft muck soil stockpile located in the southwest corner. The shaft muck was used to construct the south slope of the WRP.

Disposal of non-rock waste generated during closeout/closure was controlled to minimize long-term settlement. Materials were placed in loose lifts not exceeding 12 inches and compacted with surrounding soil. Hollow items, such as pipes, conduits, tanks, and vessels, were either placed in disposal trenches and flow-filled with a soil/cement slurry or filled with suitable clean earthen material to eliminate unsupported voids.

Contaminated soil and pond sediments, excavated as part of the reactivation of the mine, were the first materials placed in the newly constructed clay-lined disposal cell on the WRP. after these materials were consolidated, the WRP slopes were finish-graded. Historical phases used temporary

erosion control materials (e.g., Curlex® or other surface stabilization materials) ; however, the expanded disposal cell will use a permanent 52-inch cover system consisting of a 12-inch compacted clay radon barrier, 28 inches of on-site soil, and a 12-inch rock mulch admixture for long-term erosion protection.

The mound of shaft muck (soil stockpile) that formerly occupied the southwest corner of the WRP was found to have levels of radiation at or below background and supported healthy volunteer vegetation, so it was used to reshape the south slope of the WRP. Results of soil tests (Appendix D) show that the shaft muck has weathered to soil consistency and classifies as low to moderate plasticity clay and clayey sand (loam in USDA classification), like the soil that covered the ore stockpile, on which two feet of cover supported healthy volunteer vegetation.

### 4.4.2 Disposal Cell and Expansion

The disposal cell, which was constructed atop the WRP, is the permanent repository for contaminated pond sediments, soils and demolition debris generated by mine site closeout/closure activities. RGR constructed the current disposal cell during the mine reactivation phase (2018-2019), according to an approved design. This initial cell was constructed within the 13-acre footprint of the WRP. The existing disposal cell was filled to near-capacity by the contaminated materials (sediments and soils) excavated from MWTU pond basins, stormwater ponds, and other designated locations within the Mine Permit area. As of April 2022, the disposal cell had reached a filled volume of approximately 99,300 cubic yards (RGR, 2021). No new material has been placed within the disposal cell since 2020.

To accommodate the further remediation of the site during closeout/closure, the expanded portion of the disposal cell will be located east and north of the existing disposal cell and WRP at a nominal bottom elevation of 7,340 ft (Figure 4-1). The expanded cell will be up to 12 acres in area, which brings the total permanent containment footprint of the WRP plus disposal cell to 25 acres. A low permeability liner, consisting of not less than 1 ft of compacted clay soil (CL, CH, or SC soils per USCS classification), will be constructed under the expanded disposal cell to protect regional groundwater. Construction quality control (CQC) and construction quality assurance (CQA) plans shall be submitted to NMED for approval a minimum of 30 days before the clay liner construction. Within 60 days after liner completion, a CQA report and as-built plans shall be submitted to NMED.

This expanded disposal cell provides for permanent, engineered disposal of multiple waste streams. As illustrated in Figure 4-1 and Table 4-4, it will serve as the repository for contaminated pond sediments, radiologically contaminated soils, non-hazardous diesel-impacted soils generated during corrective action activities, and demolition debris generated during mine closeout/closure. If additional waste streams or more complex waste mixtures are identified during ongoing characterization, they will be evaluated using this same multi-parameter waste classification process to determine waste management and disposal requirements based on applicable regulatory criteria. The final position and precise dimensions of the expanded closure cell will be confirmed after closeout/closure activities are complete.

To date, no demolition debris has been identified as containing Resource Conservation and Recovery Act (RCRA) Subtitle C hazardous waste. Similarly, a comprehensive assessment of diesel-impacted soils (EA, 2026f) confirmed that these materials do not meet the definition of hazardous waste under RCRA, as they are not listed wastes and do not exhibit hazardous characteristics (ignitability, corrosivity, reactivity, toxicity per TCLP). A spatial analysis confirms that elevated diesel concentrations (exceeding the NMED industrial SSL of 3,000 mg/kg TPH-DRO) do not spatially coincide with radiological hotspots (Ra-226 > 20 pCi/g). Therefore, the material does not constitute a mixed radioactive and RCRA hazardous waste. In areas where both contaminants co-occur (e.g., Mine Compound), diesel concentrations remain well below the SSL (≤170 mg/kg). The expanded disposal cell's overall design—including its low-permeability clay liner, radon-attenuating cover, and long-term monitoring—is technically compatible with the co-placement of both waste streams. Limited quantities of asbestos-containing material (ACM) identified during previous site activities and have been removed and disposed of by a certified asbestos abatement contractor at a properly permitted offsite disposal facility. Any additional ACM encountered during mine closeout/closure will be managed in accordance with applicable State and Federal regulations, removed by a certified asbestos abatement contractor, and disposed of at a properly permitted offsite facility.

After waste placement and final grading, an engineered cover will be placed over the waste material. This cover will provide a barrier to reduce water infiltration, protection from erosion, support of vegetation, and radon attenuation. Extensive modeling for unsaturated flow, radon emanation, and frost penetration has been completed to finalize the cover design, as detailed in the *Expanded Disposal Cell Design* report (Appendix K, EA, 2026c).

The optimized cover system uses a 52-inch passive store-and-release configuration designed for the site's semi-arid climate. From top to bottom, the cover consists of 12 inches of rock mulch admixture, composed of 30 percent gravel and 70 percent soil, for wind and water erosion protection; 28 inches of compacted on-site soil for moisture storage and frost-depth buffering; and 12 inches of compacted clay as the primary radon and infiltration barrier. The system limits radon-222 surface flux to 13.99 pCi/m²/s, below the 20 pCi/m²/s regulatory limit, and restricts deep percolation to a design-basis rate of 0.40 inches per year.

### 4.4.3 Ore Pad Working Surface Removal

The ore pad material will be excavated by loader and hauled by truck to the disposal cell, alongside other cleanup related materials, in accordance with the Reclamation and Post-Reclamation Radiation Work Plan (ERG, 2020). A radiological characterization of the Ore Pad (AVM, 2023) was performed in 2023. Estimated quantities to be removed are found in Table 4-4.

### 4.4.4 MWTU and NSWP

The sediments in the Mine Water Treatment Unit (MWTU) Ponds #1 and #4 through #8 have been excavated and placed in the approved 11.5-acre disposal cell, as described in Section 4.4.2. They contained low levels of uranium, radium, barium sulfate and other constituents in the sediments from the mine and mine water treatment circuit described in Section 2.4.2 and Appendix D.

MWTU ponds were allowed to dry by natural evaporation, then the pond sediments were removed until residual gamma readings in the underlying soil met the soil cleanup standard (Appendix D).

A subsequent radiological characterization of the MWTU (AVM, 2024) was performed in 2024 that identified small, localized areas of cleanup that remain to be removed to the disposal cell. These estimated quantities for these remaining areas are provided in Table 4-4.

Once the Ore Pad is removed, the NSWP will be excavated to clean (background) radium values, with the contaminated materials being placed in the disposal cell (when expansion is approved).

MWTU Ponds #2 and #3 are lined with a double HDPE membrane system and are used for the evaporation of contaminated groundwater, surface water runoff, and other wash-water generated on site. These two ponds will be used during closeout/closure until groundwater abatement objectives have been achieved. When no longer needed, any newly generated pond sediments will be removed and the pond liners will be removed and placed in the disposal cell, then the hydraulic controls and related structures including foundations in the pond area will be demolished.

The NSWP sediments have not yet been removed. They will be excavated and placed in the disposal cell like the MWTU pond sediments.

After the hydraulic control structures of the ponds are demolished and all debris is removed, clean berm soils, not exceeding MMD's 2016 Joint Guidance standard of 5 pCi/g Ra-226 above background (MMD and NMED, 2016), will be used to fill the pond basins. Soil will be spread and compacted in lifts not to exceed eight inches. The area will be regraded to match final design grade (Appendix A, Drawing Sheets CL 07A and CL 08).

### 4.4.5 Affected Areas

Affected areas outside the immediate mine boundary will be reclaimed in strict accordance with 19.10.5.507.A NMAC and 19.10.1.7.R(1) NMAC (NMAC, 2001a; 2001b). Pursuant to 19.10.1.7.A(3) NMAC, an "affected area" is defined as any area outside of the designated permit area where land surface, groundwater, or air resources are impacted by mining operations conducted within the permit area (NMAC, 2001b).

RGR is currently identifying these affected areas and will continue to characterize and survey surrounding lands in accordance with the agency-approved *Reclamation and Post-Reclamation Radiological Survey Work Plan* (ERG, 2020a). Current delineation efforts are focused on characterizing contiguous lands surrounding the facility, with specific emphasis on identifying and bounding areas potentially impacted by windblown or water-borne radiological constituents.

Borrow Area B

Borrow Area B is situated on land that RGR owns but it is outside the permit boundary (Figure 1-2). No mining occurred on this land, and no activities were performed that were related to mining. Borrow Area B was used to supply the clay required to construct the 2-foot-thick clay cap on the west and northwest slopes of the WRP. Borrow Area B is comprised of a shallow pit and access road. The depression is presently being used as a stock pond and has 3:1 slope. The pit and access road will be regraded and revegetated according to Appendix F.

Borrow Area B was opened to supply these materials in the 3rd quarter of 2018, shortly after these specific clay materials were exhausted in Borrow Area A. Borrow Area B was reopened in 2020 to provide these same heavy clays to construct the 2-ft thick cap covering the disposal cell after it had been filled to near-capacity. RGR does not intend to use any more material from Borrow Area B because the supply of clay materials appears to be nearly exhausted.

There was some prior gamma survey conducted in the vicinity of Borrow Area B. Trinitech conducted a soil investigation of the areas west and north of the mine site in 2012 to investigate environmental dispersal of uranium from the Mt Taylor Mine (Trinitech, 2012) (Appendix D.2). Sixteen soil samples were collected and analyzed along arroyos that drain the mine property. Gamma dose rates were also measured. The conclusions of the memo indicated that no discernable dispersal of uranium from the mine property was detected.

Four soil samples were collected and analyzed in 2012 within the area of Borrow Area B location: MTE-12 to the west, MTE-13 and -14 to the south and MTE-6 to the west (Figure labeled "April 23, 2012, Soil Sample Locations", Appendix D.2). Uranium concentrations were below 1 pCi/g except for MTE-13 (1.4 pCi/g). Radium-226 concentrations were below the background of 1.8 pCi/g except for MTE-13 (2.7 pCi/g). All radium-226 values were below the accepted soil cleanup standard (background +5 pCi/g) limit of 6.8 pCi/g. Further gamma dose rates of these four samples were less than the Post Reclamation Radiation Level of 24 urem/hr, which is equivalent to 6.8 pCi/g. These four samples were located near drainages, where uranium dispersal from the mine would have a higher probability of accumulating.

A radiation characterization survey will be performed, as needed, for Borrow Area B and any contaminated soil will be removed so that the area meets the soil standard. Borrow Area B will be graded and revegetated according to Appendix F.

Continental Divide Substation Area

The electrical substation, located north of the Service Building (Figure 1-2), is within the permit boundary but is under the control of the Continental Divide Electric Cooperative and Public Service of New Mexico. Before final closeout, a radiation characterization survey will be performed, and any contaminated soil will be removed and placed in the disposal cell so that the area meets the soil standard. RGR will work with the substation owners on any potential reclamation and revegetation site work.

County Road 334

Existing NM 334 and its right-of-way through Section 24. The right-of-way is not under RGR now nor during mining. This surface is dedicated to public use and is not subject to reclamation or PMLU considerations under the Mining Act. A radiation characterization survey was performed in 2025 (AVM, 2026), and any contaminated soil will be removed so that the area meets the soil clean up standard. No revegetation is expected as the area is comprised of a gravel roadway. RGR will work with the Cibola County Road Maintenance Department to re-establish the roadway once contaminated materials are remediated.

San Lucas Canyon Outfall

Outfall 001 is located at the northern terminus of the former treated water discharge pipeline within San Lucas Canyon. Historical environmental investigations conducted between 2013 and 2015 evaluated soils, groundwater, surface water, sediment, and downstream impoundments and generally concluded that historical treated mine water discharges did not result in significant downstream environmental impacts requiring additional characterization at that time. As part of the mine closure program, RGR is planning additional characterization of the area immediately downstream of Outfall 001 to further evaluate localized elevated gamma radiation identified during the 2020 radiological survey. Additional information regarding the historical investigations and planned characterization is provided in the Outfall 001 Historical Summary and Planned Characterization Technical Memorandum (Appendix M: EA, 2026e).

### 4.4.6 Excavation and Disposal of Contaminated Soil

#### 4.4.6.1 Waste Characterization and Management Strategy

RGR's waste management strategy is based on extensive site characterization data rather than a rigid assumption of only two waste classes. Characterization data from the Mt. Taylor Mine indicates that the site does not contain complex hazardous mixtures, heavy metal-organic wastes, or regulatory "mixed wastes." The diesel-impacted soils onsite are non-hazardous under the Resource Conservation and Recovery Act (RCRA) All identified contamination exceeding established cleanup standards will be remediated and placed in the expanded disposal cell.

#### 4.4.6.2 Radiological Contamination and Cleanup

As is typical for a uranium mining operation, radiologically impacted materials associated with historical mining activities are present at several locations within the Mine Permit boundary. These areas include the Waste Rock Pile (WRP), Mine Water Treatment Unit (MWTU) areas, Service and Support Area (Mine Compound Area), Ore Pad Area, stormwater retention ponds, and limited areas north of Marquez Arroyo associated with historical windblown contamination. Since 2023, RGR has completed extensive radiological characterization investigations throughout the Site to identify the nature and extent of radiologically impacted materials, estimate impacted material volumes, support remedial planning, and facilitate mine closeout/closure activities. The radiological characterization reports are provided in Appendix D.1.

Investigative radiation surveys and soil sampling were initially performed in 2012 (Appendix D.1) and have continued through 2026. These investigations established background concentrations of radium, characterized radiologically impacted soils and materials, and provided the information necessary to support reclamation and closeout/closure planning. Background concentrations resulting from naturally occurring radium unrelated to mining activities were established through sampling conducted in 2007 and 2012 and are incorporated into the Mine Permit and DP-61. The approved background concentration for Ra-226 is 1.8 pCi/g.

Radiologically impacted soils and materials will be managed in accordance with the 2016 Joint Guidance for the Cleanup and Reclamation of Existing Uranium Mining Operations in New Mexico (MMD et al.) and the approved Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands (ERG, 2020a). Based on the approved background concentration of 1.8 pCi/g Ra-226, soils exceeding the Site investigation and cleanup criterion of 6.8 pCi/g Ra-226 will be excavated, as appropriate, and placed in the disposal cell. Final status surveys will be conducted, as appropriate, to verify that remediation activities have achieved the applicable cleanup criteria. The radiological characterization investigations and final status surveys completed to date will be used to support implementation and verification of mine closeout/closure activities.

#### 4.4.6.3 Diesel-Impacted Soils

Along with the remediation of uranium-contaminated soils, RGR will remediate the remnants of historical diesel spills located in the vicinity of the compressor bench (Figure 1-2) (Ensero, 2021a).

- **1991 Spill:** Originally reported while reactivating and flushing a previously abandoned potable waterline connected to the Car Shop water tanks (RGR, 1991). The area was subsequently remediated through removal of contaminated soil and seven underground storage tanks (RGR, 1992). The remediation was completed, and no further remedial actions are anticipated.

- **2019 Spill:** A diesel spill was reported while RGR was reactivating facility piping (RGR, 2019a). A limited inspection indicated petroleum hydrocarbons were detected in the riser pipes, a portion of the potable waterline by the risers, the red-lid manholes, the Car Shop potable water system, and the surrounding ground (RGR, 2019b). The source and extent of the petroleum hydrocarbon contamination continues to be investigated through the ongoing Diesel Investigation, which will support development of the corrective action plan.

NMED has approved the placement of these soils in the disposal cell (RGR, 2023a). RGR submitted a corrective action plan (CAP) to NMED in 2021 (Ensero, 2021a), and based on NMED comments, an updated CAP will be submitted in 2026.

#### 4.4.6.4 Disposal Cell Design and Waste Compatibility

The expanded disposal cell is engineered to safely consolidate soils impacted by diesel and radiological materials within a single containment unit. Because the primary diesel release area does not overlap with radiological hotspots, and any minor overlapping areas remain well below

NMED screening levels, these materials do not classify as mixed waste under RCRA or the Atomic Energy Act. The integrated design and compatibility framework relies on the following elements:

- **Containment Compatibility:** An engineered cover and liner system effectively isolates the waste. Published data confirms that the high-density polyethylene (HDPE) liner system is chemically and structurally suitable for long-term contact with the expected concentrations of weathered petroleum hydrocarbons.
- **Material Suitability:** The diesel-impacted soils contain only weathered hydrocarbons and lack free-phase product. This allows them to meet standard engineered compaction requirements without the need for specialized blending.
- **Placement Controls:** To ensure safe handling, diesel-impacted soils will be segregated during excavation, staged on impervious surfaces, and sampled to confirm their non-hazardous status. Their final location and depth within the disposal cell will be strictly documented.

This consolidated approach effectively isolates both waste streams from the environment and prevents surface water infiltration. Bolstered by a 70- to 95-foot natural geologic separation from regional groundwater, this integrated strategy minimizes long-term environmental risk and simplifies post-closure institutional controls.

#### 4.4.6.5 Excavation and Material Handling Operations

Access to the mine is controlled by fences, locked gates, and surveillance to prevent public exposure. Administrative and physical controls are implemented to maintain radiation exposures to levels as low as reasonably achievable (ALARA). Occupational exposure controls and monitoring (29CFR§ 1910.1096; OSHA, 2019) will continue throughout closeout/closure activities.

After the facilities demolition is complete and debris has either been staged (Figure 4-2) or placed in the disposal cell, soil excavation will commence. Gamma readings, correlated against Radium-226 soil samples, will be collected continuously during excavation. Contaminated soil in large, unobstructed areas will be excavated, loaded, and hauled to the disposal cell by truck or scraper. Smaller or obstructed areas of soil will be removed by loader, excavator or grader, and either windrowed for scraper pickup or loaded onto trucks for placement in the disposal cell. A final status survey consisting of independent laboratory analysis of soils from all remediated areas will be used to verify that soil remediation is complete. The technical specifications for contaminated soil earthwork are included in Appendix C.4.

### 4.4.7 Finish Grading

After demolition, soil cleanup, shaft and well plugging, and backfilling are complete, the mine site will be regraded as indicated on Appendix A Drawing Sheets CL 07A, CL 07, CL 08, and CL 14. The reshaping of the land will provide controlled drainage and will aid in the establishment of new vegetation. Grading will be adjusted as needed to remove obstacles or surface depressions that

might obstruct or divert runoff from the intended flow directions. The technical specifications for grading are included in Appendix C.4.

## 4.5 Revegetation

Following regrading, areas that have been disturbed by Mt. Taylor Mine operations and soil cleanup will be revegetated in accordance with the Revegetation Plan and Monitoring Protocols (Cedar Creek, 2025, Appendix F). Revegetated areas include the existing and expanded disposal cell area, the ore stockpile pad and runoff retention pond area, the mine water treatment pond area, borrow areas, and locations surrounding the demolished facilities within the service and support area. The SSWP bottom and other areas where mining-related features are retained (e.g. buildings and roads) will not be revegetated. RGR provided stormwater and erosion monitoring specifications for the areas that will not be revegetated in a Post-Closure Monitoring Plan (EA, 2026d; Appendix H).

Preparations for revegetation and the selected seed mix will be directed toward establishing a vegetation community that can thrive at this site and that can support grazing of livestock. Plants native to the general area will be used as much as possible to provide for long-term stability of the soil and vegetation communities. Plant species that provide rapid initial cover will be used in the seed mix to achieve initial soil stabilization. RGR may use irrigation water, as necessary, during drought situations only within the first three years after seeding to ensure the establishment of vegetation. Water for this irrigation will be provided by RGR's wells in the Point Lookout formation.

Runoff control during regrading and revegetation will use the most appropriate technology available at that time, including methods recognized by the NRCS or the International Association for Erosion Control. Measures that use present technology include check dams constructed of hay bales, geotextile silt fences secured in shallow trenches, and water bars across the disturbed area and perpendicular to the slope. Tobacco net, Curlex® or similar net-and-fiber mats might be used as required for protection of surfaces susceptible to rilling or wind erosion. The specific measures applied to revegetated surfaces will be based on the method most appropriate for the seeding method, erodibility and depth of the soils, degree of slope, proportion of large rocks at the surface, roughness of the surface, and anticipated rainfall.

Locations of temporary runoff controls will be selected, consistent with the Stormwater Pollution Prevention Plan (SWPPP), to slow down or divert runoff, trap sediment, and provide improved conditions for germination and plant establishment. Once revegetation has been achieved, temporary erosion control measures that have not disintegrated will be removed.

### 4.5.1 Revegetation Species

The predominant native grass species in the area is blue grama (NMEI, 1974); therefore, this species will be the primary species in the revegetation seed mix (assuming it is readily and economically available at the time of closeout/closure). The list of proposed species was optimized for the Mt Taylor mine site's specific soil and climate conditions (Appendix F).

### 4.5.2 Seedbed Preparation and Seeding

The regraded surfaces will be prepared for seeding by scarifying the surface and creating minor depressions to provide a proper seedbed. Seed will then be applied by either rangeland drill or broadcast. Broadcast seed will be incorporated into the growth medium by hand raking or some mechanical means such as heavy chains dragged behind tracked dozers.

*Amendments.* Organic soil amendments will be applied on a location-specific basis, taking into consideration the properties of the soil at that source. The material specifics and applications rates for the proposed amendments are described in Appendix F.

### 4.5.3 Seed Origin and Quality

Seed for the dominant species of grasses and shrubs that are indigenous to the mine area are available commercially and will be secured through those sources. All seeds must be certified, and each seed bag must have attached to it a complete label with certification information.

### 4.5.4 Revegetation Success

*Technical Standard* - The primary post mining land use is anticipated to be grazing, therefore, revegetation success in revegetated units will concentrate on four performance standards 1) vegetative ground cover, and 2) diversity, 3) woody plant density, and 4) productivity. Revegetation efforts will be considered successful when the following criteria have been met. The reference areas will be sampled along with the revegetation to provide a suitable comparison each year of assessment. In this manner, the success criteria outlined in the Revegetation Plan and Monitoring Protocols (Cedar Creek, 2025, Appendix F) is dynamic and adjusts to climatic conditions.

*Monitoring* - Monitoring of revegetated areas will be conducted on a periodic basis in accordance with the Revegetation Plan and Monitoring Protocols (Appendix F). Success of both germination and establishment will be dependent in large part on the moisture received in the summer and winter months and variations from year to year. Since establishment of vegetation is a function of its ability to reproduce, vegetation will also be assessed for its reproductive status, as well as its overall vigor. The survey will be conducted by a qualified vegetation specialist. Survey results will be analyzed and summarized to aid in determining the need for any changes in management practices or the need for reseeding or other supplementary practices. Less formal monitoring will be conducted throughout the year by RGR personnel to identify conditions in the revegetated areas that may require attention.

### 4.5.5 Management and Contingency Plans

After revegetation efforts have been completed, management of the revegetated areas will follow the Revegetation Plan and Monitoring Protocols (Cedar Creek 2025, Appendix F) and will include:

- Instruction of staff in measures to protect revegetated areas
- Posting of signs to warn against disturbance

- Placement, and replacement as necessary, of erosion controls
- Supplementary seeding of areas as necessary
- Periodic inspections and monitoring

Revegetation efforts will be repeated until successful. If results of annual monitoring indicate failure in all or part of a revegetated area, RGR will either supplement work already accomplished or revegetate the affected area, as appropriate. Efforts will be modified, as necessary, depending on what the cause of the failure is determined to have been.

## 4.6 Erosion Protection

The purpose of erosion monitoring of the disposal cell, WRP, SSWP, facilities and roads is to maintain the integrity and effectiveness of the disposal cell cover and stormwater retention or diversion measures.

Monitoring of the disposal cell /WRP includes conducting best management practices (BMPs) that include conducting inspections and making repairs as necessary to correct the effects of settling, erosion, or other significant events that may alter the effectiveness of the cover. Maintenance will prevent run-on and runoff from eroding or otherwise damaging the final cover.

Maintenance will involve repairing eroded areas by replacing lost soil material and reseeding. RGR considers any rill exceeding 6 inches of depth to be significant and requires soil replacement. Repairs will entail adding soil (in six-inch lifts and compacted) to the cover of the disposal cell. Lesser erosion will be addressed by regrading. Additional erosion control BMP's will be added where needed. These will include berms, silt fences, erosion blankets, hay bales and other water flow controls to minimize soil loss until vegetation becomes established.

Visual inspections of the ground surface will be carried out to monitor the physical stability of the disposal cell, WRP, and other reclaimed areas. Findings of the visual inspection and changes of the ground surface will be evaluated using professional judgement, informed by comparison to the closure criteria. This information will be used to generate a professional assessment of the physical stability of the disposal cell and WRP. Exceedances of the monitoring criteria will trigger geotechnical review and may or may not require corrective actions based on site-specific conditions. This may include a change in the frequency of monitoring.

### 4.6.1 Protection of the Existing Waste Rock Pile Surfaces

Erosion modeling using the Revised Universal Soil Loss Equation (RUSLE) performed for the original CCP submittal (RGR, 1998) showed that the maximum annual soil loss rate on the un-reclaimed WRP is only 0.02 T/acre/yr and would be reduced to less than 0.005 T/acre/yr after revegetation of the soil cover.

The analysis examined several base management scenarios, from smooth bare slope surface to 4-year-old vegetation on the modeled slope. For the modeled slope, representing the worst case for the WRP, 350 ft long at 20% slope, the best erosion protection is achieved by use of hay mulch.

The predicted soil loss is 0.77 t/ac/yr using hay mulch, compared to slightly higher soil loss of 0.82 t/ac/yr using rock mulch or gravel. For comparison, with vegetation after four years the predicted loss is 4.3 t/ac/yr, and a smooth bare surface is predicted to have 5.6 t/ac/yr soil loss. Therefore, RGR's use of certified weed-free hay mulch will provide the best slope protection while also encouraging vegetation of the WRP cover.

The WRP has been reshaped to avoid concentration of runoff and maintain sheet flow over the pile slopes. Erosion control blankets used in conjunction with revegetation should provide adequate interim protection of the 5H:1V and flatter slopes. If additional erosion protection is needed for surfaces on the WRP that are susceptible to erosion due to high runoff velocities or concentrated flows, such as steep slopes or drainage swales, riprap will be applied. Riprap screened for minus five inches with average particle diameter (d50) of not less 2.7 inches will be applied at least 0.5 ft thick in the bottom 1/3 of steeper slopes and as water bars in swales. Riprap will consist of basalt or equivalent rock.

Information on drainage structures and erosion protection design for the existing WRP is provided in Appendix B. Design runoff and shear calculations were prepared as part of the original CCP in 1998 (RGR, 1998). The updated erosion calculations for the expanded disposal cell design has been provided in the *Expanded Disposal Cell Design* report (Appendix K; EA, 2026c). The design will address erosion protection for the ultimate build-out size and shape of the disposal cell surfaces.

### 4.6.2 Arroyos

There are three arroyos at the mine site. There is a northern surface water diversion channel located north and east of the manway shaft and ore stockpile areas, which intercepts and diverts runoff northward to the Marquez Arroyo. The middle arroyo was largely filled in during site construction, but its remnants lead to the SSWP north of the WRP. The middle arroyo has a very small watershed; therefore, it receives little runoff. The southern arroyo (south diversion channel) was diverted at the time of mine development to run along the south side of the WRP.

Hydrologic analyses using the HEC-1 and HEC-2 models (Appendix B) show that the Marquez Canyon arroyo will convey the 24-hour, 100-year flood. These analyses show that the design flood water and energy surfaces are well within the arroyo banks in both cases, indicating that there should be no out-of-bank flow during the design flood and that the arroyo morphology appears to be in equilibrium with much larger runoff events.

The southern arroyo (south diversion channel) was diverted at the time of mine development to run along the south side of the WRP. The south diversion channel is currently in design. The New Mexico Department of Transportation (NMDOT) drainage criteria, as shown in their Drainage Manual, using the Simplified Peak Discharge methodology or the NRCS Unit Hydrograph methodology within the US Corps of Engineers Hydrologic Engineering Center-Hydrologic Modeling System (HECHMS) was used to develop flow rates and volumes. Existing development condition hydrology is the only scenario analyzed. Existing condition channel hydraulics were modeled using US Corps of Engineers Hydrologic Engineering Center-River Analysis System (HEC-RAS). Conceptual erosion control alternatives were analyzed for the south channel based

on NMDOT methodology to comply with mining requirements and regulations. Final condition hydraulics will be evaluated for the alternative selected and included in preliminary and final construction plans.

The north diversion channel, located north and east of the manway shaft and ore stockpile areas, intercepts and diverts runoff northward to Marquez Arroyo. The hydraulic analysis and design for the north diversion channel will be submitted at a later date. This is because closeout/closure activities will alter the final site grading, and the final survey cannot be completed until the ore pad has been removed.

## 4.7 Fencing

RGR has replaced and increased the height of existing fences on the mine site to provide better exclusion of cattle and wildlife from the mine site. One chain link fence, eight feet high, encloses the MWTU and is approximately 5,000 ft in length. Another eight-foot chain link fence will be up to 4,750 ft long surrounding the WRP and expanded disposal cell, depending on its final footprint. An additional 2,000 ft fence will be installed to prevent entry into the shaft areas.

# 5.0 POST-CLOSURE ENVIRONMENTAL COMPLIANCE AND MONITORING

Through the closeout/closure measures described in Section 4.0 and the requirements of other permits listed in Table 1-1 and described in the Environmental Site Assessment (RGR, 1994a), the Mt. Taylor Mine site is expected to stay within environmental standards for air and water quality.

## 5.1 Surface Water Monitoring

Surface water releases will continue to conform to NPDES-Multi Sector General Storm Water Permit (MSGP) No. NMR05J02B (NPDES, 2021) requirements until closeout/closure is completed and the permit has been terminated. The Post-Closure Monitoring Plan (EA, 2026d) (Appendix H) outlines all post-closure surface water monitoring, maintenance, and reporting requirements.

The surface water courses across the site are ephemeral. The storm water retention ponds collect runoff during larger storm or snowmelt events but are usually dry.

## 5.2 Evaporation Pond Leak Detection

As part of the surface water and facility management strategy, RGR will monitor evaporation Ponds #2 and #3 to ensure the pond liners remain intact and no fluids leak to the ground surface. This monitoring includes:

- Visual inspections of the liner surfaces for tears, rips, holes, and other defects.
- Recording the depth of water collected in the sump of each pond and calculating the leakage rate.

Should the action leakage rate be exceeded, RGR will repair the liners as needed, which may include pond evacuation, relining, and recertification of the repaired liners. Once the evaporation ponds are no longer needed for reclamation purposes, they will be reclaimed, and monitoring will cease.

## 5.3 Groundwater Monitoring

Per the following subsections, groundwater monitoring will be completed in the alluvial and Menefee, plus the deep aquifers.

### 5.3.1 Alluvial and Menefee Groundwater Monitoring

Previous mining activity has adversely impacted the shallow groundwater at the site. RGR has been addressing detected nitrate and uranium contamination under a NMED-approved S2AP (Metric, 2010) since 2011. Findings from site investigations indicate that the shallow groundwater quality and quantity is variable throughout the mine area. In various areas of the WRP and service areas, groundwater concentrations of arsenic, boron, chloride, iron, manganese, nitrate, pH, total radium, selenium, sulfate, total dissolved solids, and uranium exceed New Mexico WQCC drinking water standards.

Site investigations performed over the years (Willowstick, 2024; Ensero, 2021b; Willowstick, 2020; RGR, 2012; Kleinfelder, 2012; Metric, 2005; Metric, 2006; Metric, 2009; RGR, 1994a; NMEI, 1974) indicate that alluvium forms a discontinuous, thin veneer over residual soil and rock of the east-dipping Menefee shales and interbedded sandstones. The alluvial soil cover is thin or absent over most of the mine site. Shallow alluvial groundwater occurs primarily in preferential pathways that occur in the paleo arroyos that lie below part of the Service and Support area and the existing WRP (Willowstick, 2020; Kleinfelder, 2012).

The unlined sewage lagoon, used from 1975 to 1982, is the primary source of perched water and alluvial saturation and believed to be the source of uranium and nitrate observed in monitoring wells (Kleinfelder, 2012). Shallow groundwater flows from the site west-northwest along the alluvial-bedrock interface, primarily in paleo arroyos in the bedrock. Upper Menefee siltstones and sandstones, east of the mine site, provide groundwater recharge to alluvium and the Upper Menefee bedrock underlying the operational areas.

In addition to seepage of sewage lagoon water, minor amounts of water from over thirty years of precipitation and surface runoff infiltration contributes to a persistent groundwater mound within the WRP. The perched water migrates downward by gravity drainage along preferential pathways created by the different material buried in the WRP and paleochannels in the top of the Menefee bedrock (now buried beneath the WRP). This perched water is hydraulically connected to the underlying alluvial sediments and Upper Menefee silty sandstones as indicated by elevated uranium and nitrate concentrations present in monitor wells completed in the upper 50 ft of the Menefee in this area.

The S2AP (Metric, 2010) remedial action is extraction and evaporation of contaminated groundwater. RGR maintains a series of shallow recovery wells and alluvial/Menefee-aquifer and monitor wells as part of the ongoing abatement. Wells are completed in a perched-water zone within the WRP, in alluvium at the bedrock contact, and in the upper 50 ft of the Menefee Formation. Six wells (MW-6, WP-5, WL-2, WL-3, WL-4 and WL-5) are currently used as recovery wells. These wells are in the former lagoon area and on the western edge of the WRP (Figure 1-6, Table 1-3).

In 2026, RGR installed two more recovery wells (RW-1MR and RW-11AR) near MW-1M and MW-11A (Figure 1-6). Elevated levels of uranium and nitrate in the groundwater were detected in these areas during the 2020 site investigation (Ensero, 2021b).

A piping system, referred to as the North Force Main (NFM), was refurbished and updated during the 2018-2019 mine reactivation period. The NFM system is located just south of the Sanitary Treatment Plant (Appendix A Drawing Sheet CL03) and is comprised of a vault, pumps, and piping. The piping is buried and connects the vault to MWTU Pond #3. Monitor well WP-5 is plumbed into the NFM system, so that water extracted from the well can be pumped to MWTU Pond #3 for evaporation. Both the NFM and the WP-5 water delivery piping were leak-tested and certified leak-free by a registered New Mexico Professional Engineer, but neither has been placed into operation.

RGR intends to connect all other recovery wells to the NFM for transferring extracted water to MWTU Pond #3, if the recovery wells produce sufficient flow to justify connection. Because the recovery wells currently produce very low flow rates, impacted water may continue to be transported from the wells to MWTU Pond #3 using a mobile water tank. The existing above-grade HDPE pipeline and NFM system will operate throughout the closeout/closure period until they are no longer needed.

Piper diagrams of monitoring well water quality indicate that groundwater quality is highly variable at the mine. Water from wells MW-1C, MW-2F, and MW-1J are sodium-bicarbonate water (the predominant cation is sodium and the predominant anion is bicarbonate). Water from these wells represent background water quality in the Upper Menefee at the mine site. These three wells are located east of the WRP and have low total dissolved solids (TDS), low sulfate concentrations, and no elevated levels of chemicals of concern at the site. Water quality of all other abatement wells are sodium chloride-type waters (the predominant cation is sodium and the predominant anion is bicarbonate) and have variable levels of elevated TDS, sulfate, nitrate, and uranium concentrations. WP-4 water quality is a mixed-type water between sodium chloride and sodium bicarbonate. Details on the water quality monitoring and impacts of ongoing abatement are reported in the most recent quarterly DP-61 groundwater report (EA, 2026b).

Additional site investigation as part of the abatement program will continue to assess the source, nature and extent of groundwater impacts in the area of the shafts, near well MW-1M, and to the west and northwest of these areas.

Uranium (U) and nitrate ($NO_3$) isoconcentration maps for the shallow groundwater within the alluvial sediments and upper Menefee Fm have been provided in the Quarterly Groundwater Monitoring Report (submitted to NMED Ground Water Quality Bureau) in accordance with DP-61 (NPDES, 1998) and the S2AP (Metric, 2010) since the third quarter of 2018. The overall shape and magnitude of U and $NO_3$ distribution in shallow groundwater was relatively consistent from 2018 through the second quarter of 2021. The only notable change over that period with respect to uranium concentration was a greater than two orders of magnitude reduction at well MW-6, declining from 150 mg/L down to 1.1 mg/L. That well is completed across a perched water zone within the Waste Rock Pile (WRP).

Beginning in the second quarter of 2021, water quality from seven new monitoring wells (all completed in the upper Menefee Fm) were added to the quarterly reporting, and the results were included in the isoconcentration maps. The additional data points revealed a north-northeasterly trending arm of the nitrate and uranium plumes that extends up to newly installed well MW-1M. Note that this extension was not an indication of recent plume migration. Rather the extension reflected the addition of data in an area that was previously not part of the monitoring network.

From the third quarter of 2021 through the most recent sampling in the second quarter of 2026 (EA, 2026b), there has been little change in the shape or magnitude of either the U and $NO_3$ distribution in shallow groundwater at the Mt Taylor mine site (Figures 5-1 through 5-4).

Sulfate concentrations for the shallow groundwater monitoring network have been provided in the quarterly monitoring reports, but isoconcentration maps were not included (nor required under

DP-61). Sulfate isoconcentration maps for the shallow groundwater system (alluvial and Upper Menefee) from the third quarter of 2018 and the first quarter of 2026 are provided as Figures 5-5 and 5-6, respectively. Similar to the uranium and nitrate isoconcentration maps, the earlier sulfate map failed to detect the north-northeast trending arm of the plume that was later identified by wells MW-1M and MW4D.

Other potential sources of shallow groundwater contamination are the MWTU ponds, the ore pad and the NSWP, but such contamination is not expected. Well MW-3, which monitors groundwater down gradient of these areas, has not shown any exceedances of nitrate, uranium, nor radium (EA, 2026b). In the area of these features, the alluvial cover is thin or absent. The mine treatment ponds have been remediated and closed except for Ponds #2 and #3, which will remain open and serve as evaporation ponds until groundwater abatement activities are complete. Ponds #2 and #3 were remediated and reconstructed with HDPE liners and leak detection systems. The ore pad is graded so that water falling on it is directed to the NSWP. The NSWP is clay lined.

The S2AP (Metric, 2010) will continue to be followed until the groundwater quality meets the WQCC water quality standards for nitrate and uranium. RGR anticipates remediating site groundwater during the closeout/closure period. As needed, monitoring could extend beyond closeout/closure. Currently, groundwater extraction is the only approved remediation method, so no additional technology is included in this CCP. However, RGR intends to conduct a feasibility study of several other treatment options that potentially could accelerate groundwater remediation. The impacted groundwater and the effects of the abatement plan are being assessed through the DP-61 monitoring program. When the abatement plan objectives have been achieved, this monitoring program will be discontinued, and a completion report will be submitted to NMED.

Once the remediation goals are achieved, all abatement wells will be plugged and abandoned, except for five alluvial/Menefee wells (MW-1M, MW-4, WP-5, MW-11A, and the recently installed MW-15) that are proposed for monitoring water quality as part of the Post-Closure Monitoring Plan (EA, 2026d) (Appendix H). These well locations are shown in Figure 1-6. All wells that shall be plugged and abandoned will be done in accordance with OSE regulations and in consultation with OSE. RGR will submit a well plugging plan for approval prior to abandonment.

### 5.3.2 Deep Aquifer Groundwater Monitoring

As required by DP-61, RGR submitted a Post-Closure Deep Well Monitoring Plan (NV5, 2020) to NMED in April 2020. DP-61 Condition 57 (NMED, 2015) requires post-closure groundwater monitoring of the Point Lookout, Tres Hermanos, Dakota, and Westwater Canyon aquifers. RGR submitted an updated Post-Closure Monitoring Plan on June 30, 2025 (EA, 2025d) that included the water quality parameters and schedule for monitoring and reporting. In that plan, five wells were selected for long-term monitoring including: DW-3 and DW-10 (PLH aquifer wells); DW-11 (THD aquifer well); and DW-14 and DW-19 (WWC aquifer wells) (Figure 1-4). However, after that plan submittal, RGR received notice on September 25, 2025 from the New Mexico Office of the State Engineer (OSE) that all of those wells, with the exception of DW-14, may be in violation of NMAC 19.27.4, which does not allow for interaquifer exchange, and may require plugging and abandonment. Also, after the submittal of the June 2025 plan, NMED has indicated that additional

wells are required near the shafts to monitor potential impacts to aquifers penetrated by the shafts. The revised list of wells proposed for post-closure monitoring now includes DW-1 (PLH), DW-14 (WWC) and three new wells installed near the shafts: DMW-1 (PLH), DMW-2 (THD), and DMW-3 (WWC). Those locations are shown in Figure 5-7. Wells included in the PCMP may need to be changed or replaced, based on ongoing site reclamation and final site closure. An updated PCMP is included in Appendix H.

## 5.4 Radiological Safety and Monitoring

### 5.4.1 Radiological Safety

Radiation safety controls and monitoring are implemented to protect workers and the public consistent with applicable aspects of OSHA standards for ionizing radiation (29CFR§ 1910.1096 OSHA, 2019) (ionizing radiation) and NMAC standards for protection against ionizing radiation (20.3.4 NMAC, 2009) associated with uranium mine sites, and the ALARA requirement in 10CFR§ 20.1101 (NRC, 1991). The controls and monitoring will be implemented pursuant to the Mt. Taylor Mine Site (Site) March 2021 Radiation Protection Program (RPP) Manual (ERG, 2021) and its subordinate standard operating procedures (SOPs). The RPP includes radiation safety organization, radiation safety training requirements, ALARA policy, radiation dose standards, access controls, radiation protection controls, radiologic surveys and monitoring for exposures, associated SOPs, and environmental radiation monitoring. Radiation work permits (RWP) are written and implemented for one-time tasks which are not included in the WPs and RPP and are not ongoing activities. Applicable elements of the RPP will be updated for closeout activities, such as excavation and handling of uranium ore impacted material, that poses increased potential for exposure to workers and the public. The ongoing radiologic characterization of surface and subsurface soil will provide data that will facilitate any update of the RPP.

### 5.4.2 Radiological Surveying and Monitoring

The Site RPP (ERG, 2021) includes radiological contamination surveys, airborne particulate and radon monitoring for occupational exposure to radioactive material via internal pathways. The RPP also includes area TLDs and gamma radiation surveys for occupational exposure to radioactive material via external pathways. Radiologic monitoring for exposure to the public in the RPP consists of environmental area TLDs, radon gas monitors and airborne particulate monitoring as needed. The radiological surveys and monitoring specified in the RPP are consistent with NRC Regulatory Guide 8.30, 8.31 and 4.14 for radiation protection (NRC, 2002a; NRC, 2002b; NRC, 1980). Where warranted, the RSO will use the data generated by occupational radiation exposure monitoring to calculate estimates of radiological dose using conventional health physics principles and methods traceable to applicable State and/or Federal regulations and regulatory guidance documents.

The May 2022 MMD/NMED-approved *Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands* for the Site (ERG, 2020a) includes surveys that will be utilized during the closeout activities. The radiologic surveys in the Site Work Plan are consistent with the *Multi-Agency Radiation Survey and Site Investigation Manual* (MARSSIM) (U.S. Department of Defense et al., 2000). Direct gamma scan and static surveys will be used for excavation control (Remedial Action Support) surveys during remediation (excavation and removal) of soils

exceeding the Ra-226 soil cleanup level. Direct gamma scan and static surveys and soil sampling and analysis will be used for Final Status Survey (FSS) for demonstrating compliance with the Site soil cleanup level following the soil remediation. U.S. EPA Method 115 (EPA, 2017) for monitoring of radon-222 emissions will be used over the uranium mine waste repository radon barrier to demonstrate compliance with the 20 $pCi/m^2/s$ radon flux emission standard.

During the post-closure period, long-term radiation monitoring will be conducted by a qualified radiation professional to evaluate the effectiveness and integrity of the Disposal Cell (DC) cover and to ensure facilities retained for light industrial and commercial PMLU meet criteria for unrestricted use.

Air Quality

Air quality impacts from Mt. Taylor Mine are minimal, resulting primarily from fugitive dust generated by truck traffic which is controlled by application of water as needed. Completion of closeout/closure measures will reduce truck traffic to occasional trips by the landowner if grazing is the PMLU. Traffic related to other continued use of mine facilities retained by the surface owners cannot be predicted at this time. Revegetation of disturbed ground and erosion protection on steep slopes will reduce other fugitive dust. There are no other sources of dust or gaseous emissions left after closeout/closure. For additional information on air quality, see page 14 of the Mt. Taylor Mine Site Assessment (RGR, 1994a).

## 5.5 Sanitary Treatment Plant Discharge

The sanitary treatment plant (STP), which has not operated since the early 1990's, will be demolished during the closeout and closure phase. The associated septic tank was inspected, determined to be in sufficient operating condition, and returned to service with the current septic system. It will remain operational through closeout. No monitoring of the septic system is planned.

## 5.6 Erosion Control and Stormwater Monitoring

After the CCP earthwork is completed and the surface water runoff controls have been installed in the area identified for commercial PMLU per the Erosion and Sediment Control Plan (RGR, 2018), RGR will initiate and continue erosion monitoring through the succeeding 12-year period, or until released under the New Mexico Mining Act.

RGR will visually inspect reclaimed land for signs of erosion and will mitigate significant erosion features to prevent soil degradation at the site. RGR will inspect drainage channels, diversion structures, retention ponds, and auxiliary erosion control measures and will repair and maintain them in accordance with the standards identified in the Field Office Technical Guides of the U.S. Natural Resource Conservation Service (NRCS), Section IV current at the time of the future erosion control monitoring activities.

Inspections will continue until the specific units are released under the New Mexico Mining Act (New Mexico, 2005). Inspections will be conducted monthly for the first year following completion of reclamation construction activities for each unit, and quarterly thereafter. Reclaimed

areas will also be inspected for evidence of erosion after storm events of one inch or greater in any one-day period.

Erosion control measures that are damaged or ineffective will be repaired or redesigned as necessary. RGR commits to using a variety of erosion control measures, as needed, if erosion control problems develop. Long-term erosion control measures will include the installation of berms, designed channels, and sediment containment structures, as necessary. Short-term erosion control measures may include, but not be limited to silt fences, hay bales, water bars, and mulching.

Monitoring methods include visual observation followed as needed by more quantitative methods that could include time-sequenced UAV-based imagery, close-range photogrammetry, silt fences, erosion bridges placed across active rills, and sediment traps at the terminus of rills. These and other methods are described in detail in *Upland Soil Erosion Monitoring and Assessment: An Overview* (BLM, 2011).

As a supplement to visual erosion inspections, ground surfaces created, disturbed, or reclaimed by closeout activities may be mapped by UAV-based imagery to document as-built topography and baseline terrain conditions. For the first three years after completion of closeout, the UAV imagery of reclaimed areas may be used as baseline conditions against which visual observations can be mapped. Based on those observations, erosion could be accurately located and quantitatively evaluated. Ideally, these observations and quantitative methods may be performed annually at the end of monsoon season.

As long as the NPDES Multi Sector General Storm Water Permit #NMR05J02B (NPDES, 2021) is active, RGR will continue to monitor stormwater discharges, as required, and operate in accordance with the Mt Taylor Mine SWPPP (Inspections Plus, 2019). RGR will inspect the entire length of all storm- and surface-water diversion channels, outfalls, the SSWP, and all associated structures for physical evidence of erosion and other damage that may compromise the integrity of the stormwater management system.

Even though the MSGP expiration date has passed, the EPA did not finalize the new 2026 MSGP before the deadline. As a result, the 2021 MSGP has been administratively continued. This means that since the mine had active coverage before February 28, 2026, the permit remains fully in force and effect until the EPA issues the new permit and requires a new Notice of Intent (NOI).

Stormwater and erosion monitoring will occur according the following schedule as listed in PCMP.

## 5.7 Vegetation Monitoring

Monitoring of revegetated areas will be conducted in accordance with the Revegetation Plan and Monitoring Protocols (Cedar Creek, 2025) (Appendix F). The revegetation liability period (the period that the owner is responsible for revegetation performance) under the MMD framework is 12 years, with monitoring evaluations conducted in Years 1, 3, 6, 9, 11, and 12. Results will be analyzed and summarized to assist in determining the need for any changes in management practices or the need for reseeding.

If it is determined at the end of the 12-year liability period that the vegetation needs additional time to mature, monitoring will continue once every three years until success evaluations are positive. Once final vegetation success is achieved and approved, routine vegetation monitoring will cease.

## 5.8 Meteorological Monitoring

The purpose of meteorological monitoring is to identify and record weather-related events, alerting RGR personnel to significant precipitation or wind events that may necessitate a site inspection. RGR monitors site-specific meteorological conditions daily using a Davis Instruments 6250 Vantage Vue wireless weather station located immediately south of the Guard House.

Weather data, including precipitation amounts, air temperature, and wind speed and direction, is recorded hourly, summarized into daily records, and transmitted via a wireless connection to a datalogger. Meteorological monitoring will continue on this hourly recording schedule for as long as post-closure monitoring activities are being performed at the site.

# 6.0 CLOSEOUT/CLOSURE SCHEDULE

The schedule for mine closeout/closure is shown in the Gantt chart in Figure 6-1. From initiation of the closeout/closure contracting process to completion of the closeout/closure activities on site is estimated to take about 5 years. The first 10 months would be taken up by project management and contractor procurement, followed by 52 months of actual construction activities on site from mobilization through demobilization.

# 7.0 COST ESTIMATE

Consistent with the Mine Permit, RGR will submit an updated detailed closure cost estimate within 60 days following approval of the CCP. The updated cost estimate will incorporate the final approved closure design, current contractor pricing, and other project-specific information available at the time of preparation.

The updated cost estimate will include the assumptions, methodologies, and supporting documentation used to develop the financial assurance estimate, including updated contractor pricing and other project-specific cost information, as appropriate.

Because the final closure design, construction sequencing, and associated closure activities remain subject to approval through the CCP review process, preparation of the detailed closure cost estimate has been deferred until completion of the CCP approval process.

# TABLES

**Table 1-1 Other Permits**

| Name of Permit | Purpose | Expires |
|---|---|---|
| **Federal** | | |
| Multi Sector General Storm Water Permit #NMR05J02B | Stormwater discharge effective 06/17/2021 industrial plant | February 28, 2026, MSGP was administratively continued in March 2026 |
| **State of New Mexico** | | |
| Mine Water Discharge Permit NMED Permit #DP-61 | Mine water discharge and retention | October 14, 2020 (in timely renewal) |
| Mt. Taylor Mine Permits NM MMD Permit #C1002RE – Revision 13-2 | Active status December 29, 2017 | Applied for revision June 2022 (22-1), awaiting approval |

(1) Water quality standards for human health, domestic water supply, and irrigation use as listed in 20.6.2.3103 NMAC

Notes:

Yellow highlighted values indicate that the water quality result exceeds the standards of 20.6.2.3103 NMAC.

-0.001 - A negative sign in front of result indicates that the analyte was not detected above the Practical Quantitation Limit (PQL).

ND = Not Detected above the minimum activity count

-- = No analytical results available for the analyte

PLSS= Point Lookout Sandstone MSH/DC = Mancos Shale/Dilco Coal THSS = Tres Hermanos Sandstone WWSS – Westwater Sandstone

| **Notes** | | | | | | Depth reported as water level, sample taken 15 feet below | | | |

Acronyms: Reporting Detection Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH)

**BOLD** Bold numbers in cells indicates a concentration was measured above RDL

***BOLD-Italicize*** Bold-italicized indicates analytes detected above the reporting detection limit (RDL) in associated quality control samples

Yellow shading in cells indicates a concentration was measured above NMWQCC-3103 Standards

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

Acronyms: Reporting Detection Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH)

**BOLD** Bold numbers in cells indicates a concentration was measured above RDL

***BOLD-Italicize*** Bold-italicized indicates analytes detected above the reporting detection limit (RDL) in associated quality control samples

Yellow shading in cells indicates a concentration was measured above NMWQCC-3103 Standards

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

2: RGR received verbal confirmation that a single discrete sample was sufficent for DW-8. During a site visit by Corey Dimond on 12-9-2025, this sampling schedule was verified.

Acronyms: Reporting Detection Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH)

**BOLD** Bold numbers in cells indicates a concentration was measured above RDL

***BOLD-Italicize*** Bold-italicized indicates analytes detected above the reporting detection limit (RDL) in associated quality control samples

Yellow shading in cells indicates a concentration was measured above NMWQCC-3103 Standards

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

**Table 2-2(a) Alluvial and Menefee WQCC Analyte Exceedances During the 2Q 2026 Sampling Event[1]**

| Analyte | WQCC Standard | Wells in Exceedance |
|---|---|---|
| **Arsenic** | 0.01 mg/L | MW-2F, MW-6 |
| **Boron** | 0.75 mg/L | MW-4, WL-2 |
| **Chloride** | 250 mg/L | MW-1M, MW-4D, MW-6, WP-5 |
| **Iron** | 1 mg/L | MW-3, MW-6, MW-4H |
| **Manganese** | 0.2 mg/L | MW-1M, MW-11A, MW-3, MW-6, MW-4H |
| **Nitrogen, Nitrate** | 10 mg/L | MW-1M, WP-5 |
| **pH** | 6-9 | MW-1J, MW-2F |
| **Selenium** | 0.05 mg/L | MW-1M, MW-5, WP-5 |
| **Sulfate** | 600 mg/L | MW-1M, MW-4D, MW-4H, MW-11A, MW-4, MW-5, MW-6, WP-5, WL-2, WL-3, WL-4 |
| **TDS** | 1000 mg/L | MW-1M, MW-4D, MW-4H, MW-11A, MW-3, MW-4*, MW-5*, MW-6, WP-4, WP-5, WL-2, WL-3, WL-4 |
| **Uranium** | 0.03 mg/L | MW-1M, MW-11A, MW-4, MW-5, MW-6, WP-5 |

*There were not enough sample water available to sample for this analyte; however, historical data indicate that concentrations at these locations have consistently exceeded the applicable standard.

WQCC = Water Quality Control Commission

| | | | | Structure and Removal Date | Foundation | Retain for PMLU |
| 48 | Trailer Houses | Modular home | Unknown | Removed (date unknown) | | |

*1 Phase I wells to be used for post-mining land use or post-closure groundwater monitoring: DW-1, DW-2a, DW-6, DW-7, and DW-8
*2 Phase III well to be used for post-closure groundwater monitoring and backup site water use: DW-14
*3 All other Phase I, II, and III wells to be plugged and abandoned
*4 MWTU Ponds 2 and 3 maintained until Abatement Plan (Metric,2010) and Post-Closure Monitoring Plan (EA, 2026d) programs are complete
*5 "Number" matches "Numbers" on Figure 1-2b

## Table 4-3 Earthwork Balance

| EXCAVATION/CUT - CLEAN SOIL | | |
|---|---|---|
| **LOCATION** | **Volume, LCY** | **Destination** |
| Borrow Area C (clayey soil, clayey sand, clay) | 58,102 | Expanded Disposal Cell - Clay Cover and Liner |
| Borrow Area C (sand, sandy clay, in-situ soil) | 70,620 | Expanded Disposal Cell – 28-inch In-Situ Soil Layer |
| MWTU Area | 141,900 | Establishing MWTU area final grades |
| Ore Pad and North Diversion Channel | 12,600 | Establishing Ore Pad area final grades |
| Service and Support Area including chiller bench and north parking lot | 56,000 | Fill in Service and Support area |
| Final Grading Around the Car Shop (Cut existing grades by 2 to 3 feet) | 9,300 | Fill for north side of Disposal Cell |
| Disposal Cell Expansion Pit | 44,000 | Waste Pile/ Disposal Cell - loam cover |
| **Total** | **392,252** | |
| **FILL - CLEAN SOIL** | | |
| **LOCATION** | **Volume, LCY** | **Sources** |
| MWTU Area | 141,900 | Rough grading for final grades |
| Ore Pad and North Diversion channel | 12,600 | Rough grading for final grades |
| Service and Support Area | 52,700 | Chiller Bench and North Parking lot |
| Fill For Shaft Plugs and Other Miscellaneous Structures | 3,400 | Chiller Bench and North Parking lot |
| Fill Needed for Disposal Cell Berms, Liners, and Cover | 121,700 | Borrow Area C |
| **Total** | **332,300** | |
| **FINAL GRADING** | | |
| **LOCATION** | **Area, SY** | |
| Borrow area C north of Marquez Arroyo | 104,850 | |
| Ore Pad | 58,225 | |
| Ore Pad Runoff Retention Pond | 9,640 | |
| Borrow Area A | 38,270 | |
| Borrow Area B | 29,800 | |
| MWTU Area | 198,416 | |
| County Road 334 | 35,150 | |
| Mine Access Road | 0 | |
| Old Ore Load-out Pit | 17,850 | |
| Shaft Areas | 18,375 | |
| Service and Support Area (less building areas) | 46,082 | |
| Chiller Bench | 20,116 | |
| Compressor Bench | 21,958 | |
| Car (Maintenance) Shop Area | 30,693 | |
| Waste Rock Pile / Disposal Pit | 93,412 | |
| Substation | 4,400 | |
| **Total** | **797,986** | |

## Table 4-3 Earthwork Balance Continued

Notes:

(1) Volumes associated with the former lagoon are included per NMED request. It is not likely that the material will be excavated and transferred to the disposal cell

## Table 4-4 Summary of Materials Scheduled for the Disposal Cell

| Excavation – Contaminated Soil, Waste Rock, and Limestone | |
|---|---|
| **Location** | **Volumes ($yd^3$)** |
| **Surface and Subsurface Soil Radiological Characterization (August 14, 2023)[1] w/ Addendum (April 1, 2025)[2]** | |
| Windblown Area | 2,135 |
| Southern Mine Compound Area | 60,100 |
| Ore Pad Soils | 70,911 |
| Buried Ore Pad Runoff Retention Pond, Filled with Waste Rock | 35,556 |
| **Treatment Pond Radiologic Characterization (June 4, 2024)[3]** | |
| Leftover Soils in Ponds 1, 4, 5, 6, and 7 | 3,000 |
| **Two Pond Sediment Pile Removal from Adjacent to Borrow Area A (December 19, 2024)[4]** | |
| Waste Pond Sediment Piles Near Borrow Source Area A | 28 |
| **North Controlled Area Soil Radiologic Characterization (June 5, 2025)[5]** | |
| North Contaminated Soil[1] with Non-Ore Pad Retention Pond | 53,000 |
| **Final Status Survey, Impacted Soil/Limestone Material Removal Area (October 20, 2025)[6]** | |
| Treated Water Discharge Pipeline (TWDP) Corridor | 440 |
| **South Controlled Area Soil Radiologic Characterization (February 2026)[7]** | |
| South Controlled Area Contaminated Soil, including County Road 334 | 26,560 |
| **Other Estimated Areas** | |
| Limestone at Point of Discharge in San Lucas Canyon | 18,000 |
| Disposal Cell Expansion Pit Area | 9,300 |
| SSWP Area | 3,000 |
| Diesel-Contaminated Soil[8] | 7,400 |
| Continental Divide Coop Substation | 1,850 |
| Sediment and Waste Rock in the Former Lagoon | 10,680 |
| **Total** | **301,959** |
| **Removal - Buildings** | |
| **Location** | **Volumes ($yd^3$)** |
| Chiller Pump Building | 319 |
| Chlorine Building | 112 |
| Shaft Heating Building | 335 |
| Glycol Heat Exchanger | 328 |
| Cooling Tower | 1,597 |
| Car (Maintenance) Shop | 10,000 |
| Water Treatment and Boiler Building | 344 |

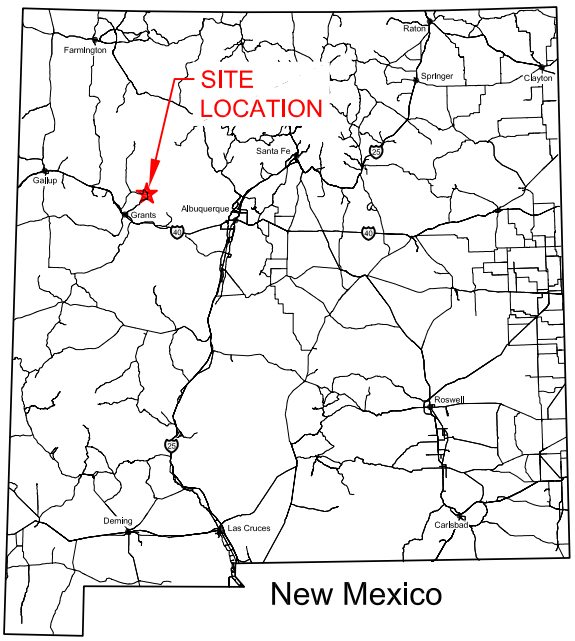

**Table 4-4 Summary of Materials Scheduled for the Disposal Cell Continued**

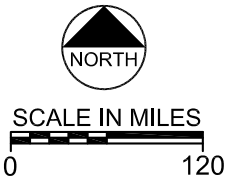

| | |
|---|---|
| Flocculant Treatment Facility | 77 |
| Barium Chloride Treatment Facility | 111 |
| Fuel Pump House | 34 |
| Mine Water Treatment Pump House | 28 |
| Mine Ventilation Structure | 702 |
| 24-Foot Shaft Headframe | 8,633 |
| **Total** | **32,862** |
| **Removal – Other Debris** | |
| **Location** | **Volumes ($yd^3$)** |
| Mine Car Rails | 22 |
| Mine Carts | 32 |
| Ore Load Pad and Wash Bay | 718 |
| Sanitary Treatment Plant | 493 |
| MWTU Pipes | 109 |
| BACL Tanks | 39 |
| South Laydown Yard Debris | 16,311 |
| South Laydown Yard Soil | 5,392 |
| 9 Truck Trailers Filled with Waste | 1,350 |
| Car Shop Yard | 4,762 |
| Treated Water Discharge Pipe | 600 |
| MWTU Pond 2 | 1,178 |
| MWTU Pond 3 | 1,500 |
| MWTU Ponds (1,4,5,6,7, 8) | 4,272 |
| **Total** | **36,778** |
| **Total Volumes ($yd^3$)** | |
| **Remaining Material Volume Scheduled for the Disposal Cell** | **371,599** |
| **20% Contingency** | **74,320** |
| **Remaining Material Volume Scheduled for the Disposal Cell Plus 20% Contingency** | **445, 919** |
| **Existing and Proposed Disposal Cell Capacity at 25-Acres** | **1,093,840** |
| **Existing Disposal Cell Volume Used** | **99,300** |
| **Excess Capacity in Disposal Cell at 25-acres** | **548,621** |

NOTES:

1. COUNTY ROAD 334, POWER POLES AND TRANSMISSION LINES, AND SUBSTATION ARE FACILITIES OWNED BY OTHERS AND ARE NOT WITHIN PERMIT. OTHER THAN CLEANUP OF CONTAMINATED SOILS, THESE FACILITIES ARE NOT SUBJECT TO CLOSEOUT.
2. DEWATERING AND PROCESS WATER PIPELINES (PARTLY SHOWN) TO BE REMOVED AND PROPERLY DISPOSED OF IF NOT NEEDED FOR PMLU WATER MANAGEMENT.
3. MWTU PONDS 2 AND 3 TO REMAIN UNTIL ABATEMENT ACTIVITIES ARE COMPLETED. ALL OTHER MWTU PONDS AND THE ORE PAD POND TO BE REGRADED.
4. CONCRETE FOUNDATIONS: EXCEPT WHERE OTHERWISE NOTED, REMOVAL OF THE STRUCTURES INCLUDES RUBBLIZATION OF THE CONCRETE SLAB AND FOUNDATIONS. ANY CONTAMINATED CONCRETE SHALL BE REMOVED AND PLACED IN THE DISPOSAL CELL. CLEAN RUBBLIZED CONCRETE CAN EITHER BE REMOVED AND PLACED IN THE DISPOSAL CELL, OR COVERED BY 24" OF CLEAN SOIL AT THE DISCRETION OF RGR.

NOTES:

1. GSE* = GROUND SURFACE ELEVATION. THE GSE FOR THE MINE SITE VARIES FROM 7280' TO 7400'.
2. (#) INDICATES THICKNESS OF GEOLOGIC UNIT IN FEET AT THE MINE SHAFT.
3. THE ELEVATIONS SHOWN ON THIS FIGURE ARE IN FEET ABOVE MEAN SEA LEVEL.

SECTION AA' - PLAN VIEW

BB'
CL05
SECTION BB'

## NOTES:

1. EXISTING CONCRETE SLAB TO REMAIN.
2. EXISTING CONCRETE SHAFT COLLAR WALLS TO REMAIN.
3. EXISTING VENT RAISE TO REMAIN AS PART OF SHAFT PLUG STRUCTURE. THE VENT RAISE TO BE BACKFILLED WITH FLOWABLE CEMENTITIOUS FILL.
4. REMOVE AND DROP ALL EQUIPMENT, FITTINGS, AND UTILITIES BETWEEN COLLAR TO SUB COLLAR LEVEL AND CLEAN SUB COLLAR OF ANY DEBRIS.
5. FLOWABLE CEMENTITIOUS BACKFILL - USE TO BACKFILL THE VENT RAISE AND SHAFT FROM PLUG AT THE SUB-COLLAR TO WITHIN 1 FOOT OF THE EXISTING CONCRETE CAP. THEN FILL THE REMAINING VOID WITH LIGHT-WEIGHT CONCRETE.
6. PLUG THE EXISTING SHAFT OPENING WITH LIGHTWEIGHT CONCRETE AND PLACE A SHAFT MARKER IN THE PLUG.
7. PLACE 2' OF CLEAN SOIL OVER THE TOP OF THE CONCRETE SLAB AND REVEGITATE.
8. 8" TO 10" PVC MONITORING PIPE WITH ACCESS CAP AT THE GROUND SURFACE.
9. UTILITY TUNNEL SHAFT CONNECTION TO BE BACKFILLED WITH THE SAME FLOWABLE CEMENTITIOUS FILL SPECIFIED FOR THE SHAFT COLLAR.

## GENERAL NOTES:

G.1 FOR CONSTRUCTION, PLACEMENT, AND MATERIAL REQUIREMENTS FOR THE FLOWABLE CEMENTITIOUS BACKFILL SEE PROJECT SPECIFICATIONS.

G.2 CONTRACTOR TO DETERMINE MEANS AND METHODS TO SAFELY FABRICATE AND INSTALL THE SHAFT PLUG AND BACKFILL SHOWN ON THIS DRAWING.

G.3 THIS IS THE APPROVED CONCEPTUAL DESIGN. THE FINAL DESIGN WILL GENERALLY FOLLOW THIS CONCEPT BUT MAY VARY IN MATERIALS AND CONSTRUCTION PER THE FINAL DESIGN OF A LICENSED STRUCTURAL ENGINEER.

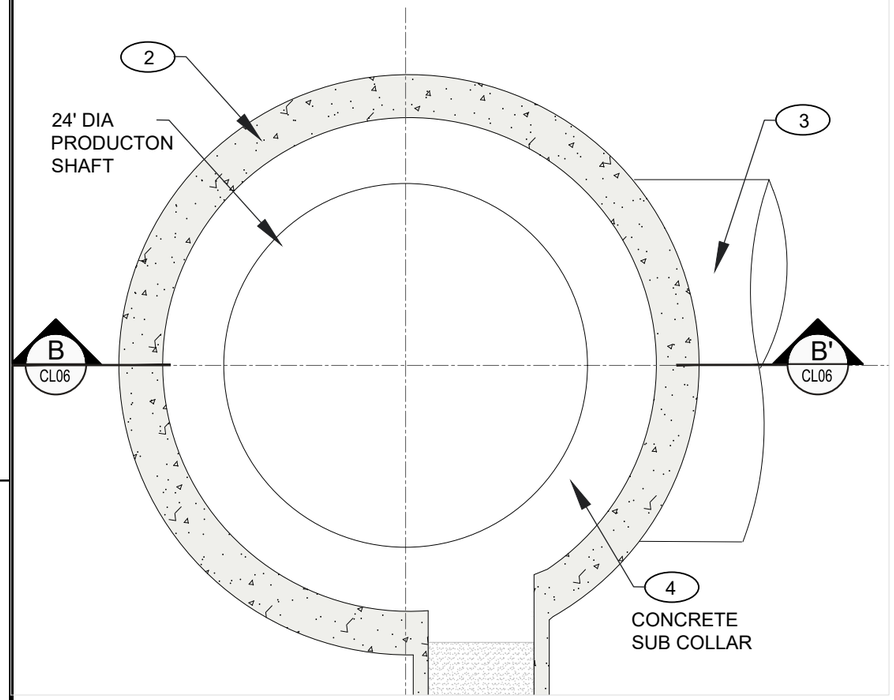
MOUNT TAYLOR MINE - *San Mateo, NM*

Prepared By: Alan Kuhn Associates LLC

Drawn By: EL Engineering Services LLC

PRINT SIZE: B

SCALE: As Shown



**MT. TAYLOR MINE**
**2022 CLOSEOUT / CLOSURE PLAN**

SHEET TITLE: FINAL DRAINAGE PLAN

SHEET NO. **CL 14**

DWG NO. **GS21-CB114-00**

REV **B**

# APPENDIX B

## Hydrologic and Erosion Analysis

B.1 Design Runoff Calculations

B.2 Surface Water Hydrologic Analysis

- Flood Hydrograph (HEC-1) Analysis
- Water Surface Profile (HEC-2) Analysis

# SURFACE WATER RUNOFF HYDROLOGIC ANALYSIS

## GENERAL PARAMETRIC EVALUATION AND MODEL INPUT DATA SELECTION FOR HEC-1 (WATERSHED RUNOFF) AND HEC-2 (FLOOD ROUTING)

**Design Storm Precipitation (Inches) for Various Frequency Intervals and Durations**

| Interval years | Duration in Hours | | | | | |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 6 | 12 | 24 |
| 2 | 0.89 | 1.00 | 1.07 | 1.20 | 1.30 | 1.50 |
| 5 | 1.03 | 1.17 | 1.27 | 1.45 | 1.60 | 1.90 |
| 10 | 1.15 | 1.32 | 1.44 | 1.65 | 1.83 | 2.20 |
| 25 | 1.38 | 1.59 | 1.73 | 2.00 | 2.23 | 2.70 |
| 50 | 1.71 | 1.91 | 2.04 | 2.30 | 2.50 | 2.90 |
| 100 | 1.97 | 2.15 | 2.27 | 2.50 | 2.73 | 3.20 |

** Duration selected must be => time of concentration, Tc

Unit Duration ~= Lg/5.5

Time of Concentration, tc
For watersheds < or = 10 sq. mi.
tc = 0.00013*(L^0.77/S^0.385)
where S = gradient
For watersheds > 10 sq. mi.
tc = 0.385*(11.9*L^3)/H
where H = elevation difference

Curve Number, CN
CN = 71 for P-J uplands (Group D) = 78 for Group B/C soils

Time to Peak Discharge, Tp, hours
Tp = 0.5*dt+Tlag
where dt = duration of excess, or computation interval
Tlag = time between center of rainfall excess and time of peak discharge

Peak flow of unit hydrograph, Qp, cfs/in
Qp = 484*Area*/Tp where Area = subbasin area in sq mi

Average Manning's Coefficient, Kn =
0.26 for uplands, general storm
0.13 for PMF and well-developed drainage courses
0.05 for uplands thunderstorm
0.073 for thunderstorm in well-developed drainage courses
For Southwest region
0.07 for coniferous forest areas
0.042 for desert terrain

# WEATHER DATA FOR THE MT. TAYLOR AREA

from National Weather Service Annual Climatological Summaries
**1986-1995**
Grants Airport (1986-1995) and San Mateo (1986-1987) Stations

# APPENDIX C

## Technical Specifications

C.2 Buildings and Pipeline Demolition

C.3 Shaft Backfill and Plugging

C.4 Earthwork

# C.2 BUILDINGS AND PIPELINE DEMOLITION

## GENERAL TECHNICAL REQUIREMENTS

### Summary of Work

Rio Grande Resources Corporation (RGR) is owner and operator of the Mt. Taylor Uranium Mine located in Cibola County, New Mexico in Section 24, T13N, R8W, NMPM. The mine site is 1/2-mile northeast of the Village of San Mateo and is accessible from New Mexico State Route 605. At the time of this submittal, the mine is on active (operating) status, but RGR has initiated closeout due to the depressed uranium market.

The mine extracted uranium ore from depths of over 3,000 feet below ground surface that connect to two 3,300-foot-deep shafts from the mine surface. The mine surface facilities are located on 285.6 acres, of which approximately 175 acres are disturbed land, and the remaining acres are undisturbed.

The disturbed land consists of:

- Support (Service and Support) Facilities
- Mine Water Treatment Area
- Treated Water Discharge Pipeline Easement
- Ore Stockpile
- Waste Pile
- Storm Water Retention Ponds (2)
- Access Road

The included work consists of demolition of buildings that will have no post-mining use, excavation of contaminated soils, well plug and abandonment, shaft and conduit closure, and disposal cell construction. Some of the mine buildings, the treated water discharge pipeline, the headframe, and other facilities have already been removed. Buildings and facilities that have post-mining use will not be removed. Facilities remaining to be removed are listed in Table 4-2. Closeout activities for the production shaft and the manway shaft are addressed in Appendix C.3.

Scrap materials from demolition (with the exception of concrete) that are not radiologically contaminated and meet the criteria for unrestricted use will be disposed of as scrap or made available for off-site sale. The surface landowner shall have the right to retain any uncontaminated demolition materials, other than concrete, for its own use, including but not limited to on-site use for post-mining applications or for off-site sale. Any demolition materials not retained on site at the written request of the surface landowner prior to demolition shall be removed by the contractor and may be used or sold by the contractor without compensation to RGR or the surface landowner. Subsequent to closeout, removal of remaining salvaged materials from the site will be at the landowner's discretion and cost.

The required work includes:

- Mobilization and demobilization of contractor's equipment
- Preparation of the work area
- Protection of potentially impacted facilities and structures
- De-energizing and removal of electric lines and equipment in facilities to be removed
- Demolition of the buildings listed in Table 4-2
- Separation and stacking of demolition debris at locations on site approved by NMED as staging areas.

Any demolition materials (other than concrete) meeting release criteria may be salvaged for sale and re-used offsite by the contractor. Workplans with drawing sheets will be prepared as each task is initiated.

**Site Survey**

Prior to mobilizing to the mine site, the Contractor shall perform its own survey of the facilities to be removed for the purposes of dimensional and volume measurements, assessment of hazards, and planning the work. The results of this site survey shall be submitted to the Project Manager for review and approval before the work begins.

**Site Restrictions**

Access to the site is limited to ingress/ egress through the main gate. All Contractor personnel and visitors shall log in and out at the guardhouse. All personnel shall wear the required safety equipment as directed by the site Safety Officer while inside the mine perimeter fence.

**Information on Existing Facilities**

Facilities to be removed include the buildings listed in Table 4-2, abandoned on-site water pipes, and hydraulic control structures of the mine water treatment ponds.

**Codes, Standards, and Regulatory Requirements**

All work must be performed according to NM State Mine Inspector or MSHA requirements. The Contractor is responsible for identifying and complying with the relevant standards and requirements.

**Site Investigation Reports & Data**

Not Applicable

## Health & Safety Practices

Work area safety is the responsibility of the contractor. The contractor shall submit and implement a Safety Plan that satisfies federal, state, and RGR requirements for the type of work being performed.

For the work under this specification, Level D PPE is required. All contractor personnel and others within the contractor's working area must be equipped with the required PPE and must comply with the requirements cited in the Codes, Standards, and Regulatory Requirements section above.

The contractor shall have a qualified Safety Officer on site during working hours. The Safety Officer shall be responsible for enforcing all safety requirements and shall have the authority to remove anyone not complying with those requirements from the contractor's working area.

## Site Safety & Emergency Communication

The contractor shall post emergency response phone numbers in the worker break area. The contractor shall always maintain an active phone line. The cell phone service may not be reliable at the mine site.

## Radiological Materials

The MMD 2016 joint guidance specifies the criteria for Ra-226 only for impacted soil cleanup. It does not specify any criteria for radiologic surface contamination limits for the release of equipment, material, and facilities. In the absence of MMD- or NMED-specific radiologic surface contamination release criteria for facilities, RGR has applied the conservative gross alpha surface contamination limit of 5,000 dpm/100 cm² contained in the MMD-approved March 2021 Site Radiation Protection Program Manual. The MMD requested that the gross alpha surface contamination limit for the PMLU at the Site would not exceed the dose limit of 100 mrem/yr.

In the 12/27/2021 Addendum to "Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands", RGR calculated the radiologic release criteria consistent with the 25 mrem/yr radiological dose-based criterion for license termination and unrestricted use from Title 20, Chapter 3, Part 4, Subpart 426.B of the New Mexico Administrative Code (NMAC). The gross alpha surface contamination limit for the release of facility at the dose limit of 25 mrem/yr was calculated to be 2,364 dpm/100 cm². For a 100 mrem/yr dose limit, the gross alpha surface contamination would be 9,456 dpm/100 cm². This is because the relationship between surface contamination and dose is linear. However, RGR proposes the gross alpha surface contamination limit of 5,000 dpm/100 cm², as specified in NRC Regulatory Guide 1.86, which is well below the 9,456 dpm/100 cm² calculated based on the 100 mrem/yr dose. In addition, the gross alpha surface contamination limit of 5,000 dpm/100 cm² is specified in the MMD-approved March 2021 Site Radiation Protection Program Manual

**Field Engineering and Surveying**

Not Applicable

**General Submittals**

Prior to commencing the work, the contractor shall submit, in a format acceptable to RGR, the following:

- **Site Safety Plan:** Including the name and qualifications of the Safety Officer
- **Demolition Plan:** – Describing methods of demolition, equipment to be used, names and qualifications of key personnel, and the project schedule.

**Construction Facilities and Field Office**

***Site Access, Field Office, Storage, and Maintenance***

RGR will provide space for the contractor's field office, laydown areas, sanitary facilities, and equipment maintenance. Existing buildings, if any, will not be available for contractor use. If needed, electrical power must be arranged by the contractor with Continental Divide Electric Cooperative. Water, both potable and non-potable, is available on site. The contractor must make arrangements with RGR for pumping, storing, and discharge of water needed by the contractor.

**Protection of Existing Facilities**

The contractor shall not use, damage, or block access to site buildings and other facilities that are in use at the time of the contractor's work or that are to remain intact for post-mining land use. Any damage or loss of use shall be repaired or compensated at the contractor's cost.

**Temporary Environmental Controls**

The contractor shall be responsible for emplacing, utilizing, and removing those measures necessary to contain contaminants, surface water and fugitive dust releases generated by the contractor's work. Such measures may include, but are not limited to;

- Fuels, solvents and lubricants storage
- Surface water diversions and erosion control materials
- Dust suppression chemicals containers
- Sanitary wastes containments
- Trash containers
- Fire suppression equipment

Wildlife, including large game animals, frequently enters the site. The contractor's workers shall do nothing to attract, injure, or otherwise interfere with wildlife. No firearms may be brought on the mine site.

## SITE WORK

### Site Preparation

The contractor shall de-energize and remove all electrical equipment and lines in facilities to be removed. The contractor shall prepare its office, equipment, and laydown areas as approved by RGR so as not to obstruct or interfere with RGR site operations or other contractors' operations.

### Demolition

The contractor shall submit a demolition plan for RGR approval prior to beginning the work. The plan shall include methods and equipment to be used, names and qualifications of key personnel, and schedule. The plan shall also describe any salvage proposed by the contractor, including materials and expected values.

### Building and Pipe Removal

The buildings shall be removed by mechanical or manual methods; no explosives may be used. The buildings are steel frames with metal siding and roofs.

No asbestos-containing materials (ACM) are currently known to be present within the site facilities. However, the contractor shall perform inspections as it considers necessary to identify potential ACM that may be encountered during demolition, renovation, reclamation, or earthwork activities. If suspect ACM is identified, the material shall be evaluated and managed in accordance with applicable federal and state regulations. Any confirmed ACM shall be handled by appropriately trained personnel, properly contained during removal and transport, and disposed of at a licensed off-site facility authorized to accept asbestos-containing waste. The contractor shall be responsible for complying with all applicable notification, handling, transportation, and disposal requirements.

### Debris Sizing and Stacking

The contractor shall prepare demolition debris for disposal. The contractor shall reduce the size of debris and sort it sufficiently for it to be classified and stacked by material type and potential re-use or salvage.

Demolition debris other than concrete shall be cut, hauled, and stacked according to shape (e.g.; beams, sheet metal) in disposal cell of the waste pile as determined by RGR. Debris shall be reduced in size to fit into the likely transport vehicle, but in any case, must not be any longer than 40 feet.

### Concrete Debris

The contractor shall remove the concrete in floor slabs of removed buildings, pond hydraulic control structures, ore bins next to the production shaft, aprons more than 20 feet beyond the shaft collars, and subgrade of mine car rails. Some concrete slabs and foundations (Table 4-2) will be broken into pieces not exceeding one-foot maximum dimension and left in place to be covered with soil.

## GENERAL QUALITY ASSURANCE AND QUALITY CONTROL

### Reviews

Not Applicable

### Inspection Reports

The contractor shall record in writing the amount of material removed in each truck-load trip ticket, as well as the total amount of material removed each working day. This record shall be subject to review and independent verification by RGR.

### Test Reports

Not Applicable

## FINAL ACCEPTANCE AND CONTRACT CLOSEOUT

### Substantial Completion

The work will be substantially complete when all site work and general quality assurance and quality control has been completed by the contractor and accepted by RGR.

### Close-Out Documentation

The contractor shall submit written documentation, in a form acceptable to RGR, that all units of work have been completed in accordance with this specification. This documentation shall include quantities of work performed in accordance with the line items in the contractor's bid schedule that have been approved in writing by RGR. The documentation shall also include the contractor's affirmation that all regulatory requirements and environmental standards applicable to the work have been met.

The documentation shall bear the signature of the contractor's officer with signatory authority.

### Final Payment

Final payment shall be made after close-out documentation has been accepted and approved by RGR.

# C.3 SHAFT PLUGGING AND BACKFILL

## GENERAL TECHNICAL REQUIREMENTS

### Summary of Work

Rio Grande Resources Corporation (RGR) is owner and operator of the Mt. Taylor Uranium Mine located in Cibola County, New Mexico in Section 24, T13N, R8W, NMPM. The mine site is 1/2-mile northeast of the Village of San Mateo and is accessible from New Mexico State Route 605. At the time of this submittal, the mine is in active (operating) status but has initiated closeout activities due to the continued depressed uranium market.

The mine extracted uranium ore from depths of over 3,000 feet below ground surface that connect to two 3300-foot-deep shafts from the mine surface. The water level in the shafts is approximately 820 feet below collar elevation.

The included work consists of construction of a plug in each shaft at subcollar level, backfilling to the collar and connected openings, and placement of concrete markers on the shaft caps. Required work includes:

- Mobilization and demobilization of the contractor's equipment
- Preparation of the work area
- Placement of new structural steel as the primary structural component of the shaft plugs
- Mixing and placement of light weight concrete, cementitious slurry, and cap concrete
- Site cleanup and removal of work debris

The work is represented in Appendix A Drawing Sheets: CL05 Shaft Closure - Manway Vent and CL06 Shaft Closure - Production Shaft

NOTE: THESE DRAWINGS SHOW THE CONCEPTUAL DESIGNS OF SHAFT CLOSURE. DETAILED DESIGN WILL BE COMPLETED BY A LICENSED STRUCTURAL ENGINEER AND MAY ALTER THE PLUG CONFIGURATIONS SHOWN HERE.

### Site Survey

The Contractor shall perform its own survey of the dimensions of the shaft collar, subcollar, and connected openings above subcollar level for the purposes of dimensional and volume measurements, assessment of hazards, and planning the work. This survey shall include an inventory of material in the shaft collars that must be removed from the shafts for salvage. The results of this site survey shall be submitted to the Project Manager for review and approval before the work begins.

**Site Restrictions**

Access to the site is limited to ingress/egress through the main gate. All Contractor personnel and visitors shall log in and out at the guardhouse. All personnel shall wear the required safety equipment as directed by the site Safety Officer while inside the mine perimeter fence.

The contractor's work area shall be enclosed with temporary fencing, selected and provided by the contractor, to restrict access to the shafts to authorized personnel only. The contractor shall prohibit entry to anyone not trained and authorized to enter the enclosed area or accompanied at all times by an authorized person.

**Work Performed by Others**

Not applicable.

**Codes, Standards, and Regulatory Requirements**

All work must be performed according to New Mexico State Mine Inspector and/or MSHA requirements. The Contractor is responsible for identifying and complying with the relevant standards and requirements.

The contractor shall implement the applicable requirements for worker fall protection including, but not limited to, 29 CFR 1926:

- 1926.501, Duty to have fall protection
- 1926.502, Fall protection systems criteria and practices
- 1926.503, Training requirements (Fall Protection)
- 1926.760, Steel Erection (Fall protection)
- 1926.800, Underground construction
- 1926.1051, General requirements (Stairways and Ladders)

**Site Investigation Reports & Data**

Not applicable.

**Health & Safety Practices**

Work area safety is the responsibility of the contractor. The contractor shall submit and implement a Safety Plan that satisfies federal, state, and RGR requirements for the type of work being performed.

For the work under this specification, at a minimum Level D PPE is required. In addition, safety measures required under the Codes, Standards, and Regulatory Requirements section and

elsewhere in federal and state regulations shall be implemented. All contractor personnel and others within the contractor's working area must be equipped with the required PPE.

The contractor shall have a qualified Safety Officer on site during working hours. The Safety Officer shall be responsible for enforcing all safety requirements and shall have the authority to remove anyone not complying with those requirements from the contractor's working area.

**Site Safety & Emergency Communication**

The contractor shall post emergency response phone numbers in the worker break area. The contractor shall maintain an active phone line at all times. Cell phone service is not reliable at the mine site.

**Radiological Materials**

The production shaft and manway/ventilation shaft are inaccessible and will be permanently closed through installation of engineered shaft plugs, backfill, and surface caps as described in this section. During shaft closure activities, the contractor shall implement the applicable portions of RGR's Radiation Safety Program Manual (RSPM) and associated procedures to ensure the protection of workers, the public, and the environment.

The RSPM and associated procedures include, but are not limited to, radiological work controls, development and use of non-routine procedures, access control and security, radiation monitoring surveys, radiation dose management, and response to incidents and emergencies involving radioactive materials. RGR's radiological consultant, Facilities Supervisor, and Reclamation Manager will provide the necessary technical support, training, and oversight; however, the contractor shall be responsible for ensuring worker compliance with the RSPM.

**Field Engineering and Survey**

The contractor shall perform surveys and measurements as required under the Site Survey section to verify dimensions of workspaces and construction materials described in this specification, the Appendix A reference drawings, and the 1974 Dravo design drawings, which will be available to the contractor for planning the work.

**General Submittals**

Prior to commencing the work, the contractor shall submit, in a format acceptable to RGR, the following:

- **Site Safety Plan:** Including the name and qualifications of the Safety Officer.
- **Shaft Plug and Backfill Construction Plan:** Describing methods of construction, equipment to be used, names and qualifications of key personnel, and the project schedule.

### Construction Facilities and Field Office

RGR will provide space for the contractor's field office, laydown areas, sanitary facilities, and equipment maintenance. Existing buildings, if any, will not be available for contractor use. If needed, electrical power must be arranged by the contractor with Continental Divide Electric Cooperative. Water, both potable and non-potable, is available on site. The contractor must make arrangements with RGR for pumping, storing, and discharge of water needed by the contractor.

### Protection of Existing Facilities

The contractor shall not use, damage, or block access to site buildings and other facilities that are in use at the time of the contractor's work or that are to remain intact for post-mining land use. Any damage or loss of use shall be repaired or compensated at the contractor's cost.

### Temporary Environmental Controls

The contractor shall be responsible for emplacing, utilizing, and removing those measures necessary to contain contaminants, surface water and fugitive dust releases generated by the contractor's work. Such measures may include, but are not limited to:

- Fuels, solvents and lubricants storage
- Surface water diversions and erosion control materials
- Dust suppression chemicals containers
- Sanitary wastes containments
- Trash containers
- Fire suppression equipment

## SITE CONSTRUCTION

### Site Preparation

The contractor shall prepare its office, equipment, and laydown areas as approved by RGR so as not to obstruct or interfere with RGR site operations or other contractors' operations. The contractor shall stage and operate its equipment to allow setback distances from the shaft collars that are appropriate for the selected equipment size, weight, and operating radius. The contractor shall prepare its working area and equipment locations to minimize traffic or materials next to the shaft collars.

### Shaft Plug Construction

The following information represents the construction of conceptual plug designs. The actual design and the construction to implement that design provided by a licensed Structural Engineer may be different for this conceptual design and shall supersede or modify this design concept.

Both the 24 ft. diameter production shaft and the 14 ft. diameter manway/ventilation shaft will be closed in the same way, illustrated in the Appendix A Drawing Sheets CL05 and CL06, in the following sequence after the headframes and collar structures are removed (by others) and the subcollar space has been freed of obstacles.

To address concerns regarding plug stability and the added weight on the legacy shaft concrete, the final shaft closure design will incorporate measures to transfer the structural loads from the shaft plug into competent host rock, such as engineered horizontal keyways, or another engineered approach determined during final design. The final design will support the plug independently of the existing shaft walls and minimize reliance on the long-term integrity of the shaft concrete or future regional water-level fluctuations. The final shaft closure design will be submitted to NMED for review and approval prior to construction.

To facilitate long-term post-closure groundwater sampling capabilities, the final plug design is expected to incorporate two structurally isolated steel monitoring ports built directly through each individual shaft plug.

A plug of light-weight concrete meeting the requirements of ASTM C 330 shall be poured to encapsulate the engineered structural steel and monitoring ports. The concrete shall have an in-place density of 90-115 pcf and a minimum compressive strength of 2500 psi. The concrete shall be placed in not more than three lifts. The first lift shall fully encapsulate and cover the base structural support and shall be vibrated to ensure a tight seal within the keyway. Successive lifts shall be not more than 1.0 feet thick.

The shaft plug concrete shall be allowed to cure for not less than 28 days before any overlying shaft backfill is placed.

**Shaft Backfill**

The remainder of the shaft above the plug, as well as connecting tunnels and raises, shall be backfilled with a cementitious slurry of soil, Portland cement, fly ash, and water shall be utilized. The contractor shall determine proportions of these components using test batches of the available materials, for acceptance by RGR before placement. The selected mix shall have a cured compressive strength of not less than 75 pcf. Sandy waste rock material from the waste pile may be substituted for the soil fraction of the mix.

**Shaft Cap and Marker**

The remaining space at the top of the shaft backfill, from top of slurried backfill to adjacent ground surface, shall be capped with not less than 1.0 feet of light-weight concrete, with a monument marker extending above ground surface.

The marker monuments shall be pre-cast 2500-psi concrete, at least two feet high and four feet wide and long, with a hand finished top surface. Both shaft markers shall be inscribed with "Mt. Taylor Mine (name) Shaft, Closed (date)."

## GENERAL QUALITY ASSURANCE AND QUALITY CONTROL

### Reviews

Not applicable.

### Daily Reports

The contractor shall prepare a written daily report of each working day. This report shall include a record of the dimensions of the shaft plug components, the volumes of materials used, and any deviations from the drawings or this specification necessitated by conditions encountered. This record shall be subject to review and independent verification by RGR.

### Test Reports

At least one test cylinder shall be cast for each lift of light-weight concrete poured. The contractor shall have each cylinder tested for density (unit weight) and unconfined compressive strength. Records of test cylinder tests shall be submitted to RGR.

## FINAL ACCEPTANCE AND CONTRACT CLOSEOUT

### Substantial Completion

The work will be substantially complete when all work required under the Site Construction and General Quality Assurance and Quality Control sections have been completed by the contractor and accepted by RGR.

### Close-Out Documentation

The contractor shall submit written documentation, in a form acceptable to RGR, that all units of work have been completed in accordance with this specification. This documentation shall include quantities of work performed in accordance with the line items in the contractor's bid schedule that have been approved in writing by RGR. The documentation shall also include the contractor's affirmation that all regulatory requirements and environmental standards applicable to the work have been met.

The documentation shall bear the signature of the contractor's office with signatory authority.

### Final Payment

Final payment shall be made after close-out documentation has been accepted and approved by RGR.

# C.4 EARTHWORK

## GENERAL TECHNICAL REQUIREMENTS

### Summary of Work

Rio Grande Resources Corporation (RGR) is owner and operator of the Mt. Taylor Uranium Mine located in Cibola County, New Mexico in Section 24, T13N, R8W, NMPM. The mine site is 1/2-mile northeast of the Village of San Mateo and is accessible from New Mexico State Route 605. At the time of this submittal, the mine is on active (operating) status, but RGR has initiated closeout activities due to the depressed uranium market.

The mine extracted uranium ore from depths of over 3,000 feet below ground surface that connect to two 3300-foot-deep shafts from the mine surface. The mine surface facilities are located on 285.6 acres, of which approximately 148 acres are disturbed land, and the remaining acres are undisturbed.

The disturbed land consists of:

- Support (Service and Support) Facilities
- Mine Water Treatment Area
- Ore Stockpile Pad
- Waste Pile / Disposal Cell
- Storm Water Retention Ponds (2)
- Access Road and other roads
- Borrow areas

The included work consists of excavation, hauling, placement, and compaction of soil and rippable rock within the mine permit area and nearby affected areas for the purposes removing contaminated soil, stabilizing slopes, and covering mine waste containment structures.

The required work includes:

- Mobilization and demobilization of the contractor's equipment
- Preparation of the work area
- Excavation of soil contaminated with low levels of radium and uranium originating from the underground mine and mine water
- Disposal of contaminated soil in the existing mine disposal cell on the waste rock pile, or in the shafts

- Expanding the disposal cell
- Reducing rock slopes
- Backfilling of the mine water treatment ponds
- Placement of clean soil cover over the waste rock pile and disposal cell
- Backfilling the mine water treatment ponds
- Finish grading of disturbed ground within the mine permit area and affected areas

The work is represented in the Appendix A Drawing Sheets, and will be developed in future workplans and drawing sets per individual tasks:

- CL07A: Final Grading Plan - Mine Water Treatment Unit
- CL07B: Final Grading Plan – Service and Support Area
- CL08: Details – Backfill in Pond areas
- CL14: Final Drainage Plan

**Site Survey**

The Contractor shall perform its own survey or calculations to determine depths and volumes of excavated soil, field control for line and grade, and depths and volumes of soil placed. The results of this site survey shall be submitted to the Project Manager for review and approval of work performed and for verification of payment quantities.

**Site Restrictions**

Access to the site is limited to ingress/ egress through the main gate. All Contractor personnel and visitors shall log in and out at the guardhouse. All personnel shall wear the required safety equipment as directed by the site Safety Officer while inside the mine perimeter fence.

**Work Performed by Others**

Prior to the commencement of this work, the shaft headframes, hydraulic control structures, and selected buildings will be removed by others.

**Codes, Standards, and Regulatory Requirements**

All work must be performed according to OSHA and/or MSHA requirements. The Contractor is responsible for identifying and complying with the relevant standards and requirements.

## Site Investigation Reports & Data

RGR has conducted site investigations to characterize the waste rock pile materials, soil contamination, and geotechnical properties of on-site soil. Reports of these studies and related data are included in Appendix D of the Mt. Taylor Mine Closeout/Closure Plan.

## Health & Safety Practices

Work area safety is the responsibility of the contractor. The contractor shall submit and implement a Site Safety Plan that satisfies federal, state, and RGR requirements for the type of work being performed.

For the work under this specification, Level D PPE is required. In addition, safety measures required under the Codes, Standards, and Regulatory Requirements section and elsewhere in federal and state regulations shall be implemented. All contractor personnel and others within the contractor's working area must be equipped with the required PPE and must comply with the requirements cited in the Codes, Standards, and Regulatory Requirements section.

The contractor shall have a qualified Safety Officer on site during working hours. The Safety Officer shall be responsible for enforcing all safety requirements and shall have the authority to remove from the contractor's working area anyone not complying with those requirements.

## Site Safety & Emergency Communication

The contractor shall post emergency response phone numbers in the worker break area. The contractor shall maintain an active phone line at all times. Cell phone service is not reliable at the mine site.

## Radiological Materials

The contractor shall implement the applicable portions of RGR's Radiation Safety Program Manual (RSPM) and associated procedures to ensure the protection of workers, the public, and the environment during reclamation activities. The RSPM and associated procedures include, but are not limited to, radiological work controls, development and use of non-routine procedures, access control and security, radiation monitoring surveys, radiation dose management, and response to incidents and emergencies involving radioactive materials. RGR's radiological consultant, Facilities Supervisor, and Reclamation Manager will provide the necessary technical support, training, and oversight; however, the contractor shall be responsible for ensuring worker compliance with the RSPM.

## Field Engineering and Surveying

The contractor shall perform surveys and measurements as required under the Site Survey section to verify dimensions, lines and grades, and construction materials described in this specification and the Appendix A referenced drawings.

## General Submittals

Prior to commencing the work, the contractor shall submit, in a format acceptable to RGR, the following:

- **Site Safety Plan:** Including the name and qualifications of the Safety Officer.
- **Contaminated Soil Excavation Plan:** Describing methods for excavating, hauling, and placing contaminated soil, including measures to be taken to control spillage and fugitive dust release during handling. The plan shall also describe equipment to be used, names and qualifications of key personnel, and the project schedule.
- **Soil Cover and Grading Plan:** Describing methods of construction for excavation, hauling, placing, and compacting clean fill soil, including equipment to be used, names and qualifications of key personnel, and the project schedule. The plan shall also include fugitive dust control and finish line and grade control.
- **Stormwater Pollution Prevention Plan (SWPPP)**: Compliant with the minimum requirements of EPA's 2012 Construction General Permit under the NPDES.

## Construction Facilities and Field Office

RGR will provide space for the contractor's field office, laydown areas, sanitary facilities, and equipment maintenance. Existing buildings, if any, will not be available for contractor use. If needed, electrical power must be arranged by the contractor with Continental Divide Electric Cooperative. Water, both potable and non-potable, is available on site. The contractor must make arrangements with RGR for pumping, storing, and discharge of water needed by the contractor.

## Protection of Existing Facilities

The contractor shall not use, damage, or block access to site buildings and other facilities that are in use at the time of the contractor's work or that are to remain intact for post-mining land use. Any damage or loss of use shall be repaired or compensated at the contractor's cost.

### Temporary Environmental Controls

The contractor shall be responsible for emplacing, utilizing, and removing those measures necessary to contain contaminants, surface water and fugitive dust releases generated by the contractor's work. Such measures may include, but are not limited to:

- Spraying of clean water for dust suppression
- Storage of fuels, solvents and lubricants
- Surface water diversions and erosion control materials
- Sanitary wastes containments
- Trash containers
- Fire suppression equipment

Wildlife, including large game animals, frequently enters the site. The contractor's workers shall do nothing to attract, injure, or otherwise interfere with wildlife. No firearms may be brought on the mine site.

## SITE CONSTRUCTION

### Site Preparation

The contractor shall prepare its office, equipment, and laydown areas as approved by RGR so as not to obstruct or interfere with RGR site operations or other contractors' operations.

### Removal of MWTU Facilities Pond Liner Anchor

The contractor shall remove the following:

- The HDPE liner systems from the Mine Water Treatment Unit (MWTU) Ponds 2 and 3.

All removed pond liner materials and debris from the hydraulic control structures shall be transported and placed in the disposal cell, as directed by RGR.

### Excavation and Disposal of Contaminated Soil

The contractor shall submit a Contaminated Soil Excavation Plan for excavating, hauling, and disposal of soil containing more than 6.8 pCi/g of Radium 226. RGR will provide field direction for the contractor in determining the lateral extent and depth of excavation required.

The contaminated soil excavated north of the CR 334 shall be disposed of in the disposal cell on the waste rock pile, as directed by RGR. Contaminated soil excavated within the CR 334 right-of-way and on the mine site south of the CR 334 right-of-way shall be placed in the disposal cell, as well.

The waste pile and some old fill (placed during mine development) contain scrap metal, rock bolts, abandoned pipe and cable, and other debris from mining. The contractor can encounter these materials buried within the waste rock and other locations within the mine area. If such debris is uncovered during reshaping, it shall be removed and reburied in the disposal cell.

RGR will provide radiological screening support to guide the contractor in assessment of soil radium content and determination of areas and depths of excavation for soil removal and for relocation to the disposal cell.

**Construction of Soil Cover**

The contractor shall submit for RGR approval a Soil Cover and Grading Plan that describes the methods for excavation, hauling, placing and compacting clean fill soil and finish grading over the mine site. The plan shall include equipment to be used, names and qualifications of key personnel, and schedule. The plan shall also include fugitive dust control and methods to verify finish line and grade control.

**Finish Grading**

All disturbed soil surfaces and constructed cover surfaces shall be finish-graded to achieve the lines and grades shown on Appendix A Drawing Sheets CL07A, CL07B, CL08, and CL14. The elevation contours shown on these drawings are representational; final elevations will depend on actual quantities of contaminated soil and clean cover soil excavated and placed.

The finish-graded surface shall conform to the direction (line) and angle of slope (grade) shown on the drawings. Verification of line and grade shall be made by land surveys directed by a New Mexico Licensed Professional Surveyor.

The finish-graded surfaces shall be free of demolition debris and depressions, ridges, rills, and other irregularities more than three inches in amplitude caused by either mining-related activities or closeout activities. On surfaces where rock will be placed for erosion protection (riprap), final grading need not achieve this standard but shall remove all irregularities of amplitude greater than the design thickness of the rock to be placed on such surfaces.

The surfaces of the disturbed areas and covers shall be bladed to provide:

- Smooth transitions to surrounding soil surfaces
- Gradual transitions in slope gradients
- Unimpeded drainage of runoff (no depressions deeper than the amplitude of the surface roughness of the soil cover)

On the final pass of surface grading, the grading equipment shall run along the contour of the slope, unless slope gradients are prohibitively steep, and shall blend the re-contoured surfaces into adjacent undisturbed areas.

### Erosion Control and General Site Drainage

The primary means of controlling erosion by runoff will be grading per the Finish Grading section. Control of surface water runoff onto or from reclaimed areas will be accomplished as part of the re-contouring and final grading. Existing natural drainage courses will be preserved and improved as necessary to remove obstacles and trapped debris.

In general, runoff will be directed to natural drainage courses and will follow natural surface gradients so that no control structures or energy dissipaters will be required. New drainage courses and swales will be not less than 10 feet wide at channel bed, not less than two feet deep, with side slopes not steeper than 4H:1V unless obstructed by natural durable rock. Diversion channels will be required only where actual cover or final slope gradients produce concentrated runoff and/or slope erosion.

## GENERAL QUALITY ASSURANCE AND QUALITY CONTROL

### Reviews

RGR shall meet with the contractor at the start of work each day to review the previous day's Daily Report and any deliverable from the contractor.

### Daily Reports

The contractor shall prepare a written daily report of each working day. This report shall include a record of the units and quantities of work performed, events or conditions adversely affecting the work, and any deviations from the drawings or this specification necessitated by conditions encountered. This record shall be subject to review and independent verification by RGR.

### Test Reports

The contractor shall measure, record and report in writing the quantities of each size of concrete and rock crushed and screened. The contractor shall report on the measured volumes, locations and thicknesses of soil, rock, and erosion control materials placed each day.

## FINAL ACCEPTANCE AND CONTRACT CLOSEOUT

### Substantial Completion

The work will be substantially complete when all work required under the Site Construction and General Quality Assurance and Quality Control sections have been completed by the contractor and accepted by RGR.

### Close-Out Documentation

The contractor shall submit written documentation, in a form acceptable to RGR, that all units of work have been completed in accordance with this specification. This documentation shall include quantities of work performed in accordance with the line items in the contractor's bid schedule

that have been approved in writing by RGR. The documentation shall also include the contractor's affirmation that all regulatory requirements and environmental standards applicable to the work have been met.

The documentation shall bear the signature of the contractor's officer with signatory authority.

**Final Payment**

Final payment shall be made after close-out documentation has been accepted and approved by RGR.

# APPENDIX D

## Soil Sampling and Laboratory Test Data

# MT TAYLOR MINE SHAFT MUCK SAMPLE LOCATIONS – 5/18/2010

Bulk samples of shaft muck from Mt. Taylor Mine waste rock pile collected on 5/18/2012 by Alan Kuhn. Locations are approximate (+/- 50 ft) based on visual reference to slopes. Splits delivered 5/18/12 to Kleinfelder Albuquerque for grain size analysis and plasticity tests. Other splits left with RGR Mine office for shipment to Energy Labs for testing of U and Ra concentration.

# APPENDIX D.2

## Field Sampling and Laboratory Test Data

Radiological Investigations

**MEMORANDUM**

Date: June 6, 2012

From: Stanley Fitch, CHP, Radiation Safety Officer 

To: Joel Lister, Mine Manager, Mt. Taylor Mine

Subject: April 2012 Soil Investigation

On April 23, 2012, a soil sampling campaign was performed to investigate possible environmental dispersal of uranium and its progeny from the Mt. Taylor Mine. A total of 16 samples were retrieved, 2 background locations and 14 locations along arroyos that drain the mine property. In addition, gamma dose rate measurements were taken.

The purpose of this investigation is to determine background radionuclide concentrations and to evaluate the potential spread of uranium and radium from the mine. To wit, soil samples were taken at various locations adjacent to drainage features (e.g., Marquez Arroyo) and in the thalwegs of these features. The background locations selected are locations MTE-1 (up Marquez Canyon next to the Forest Service Boundary) and MTE-7 (North ¼ Corner of Section 24) for grades above drainage features.

MTE-2 was selected as the background location for the Marquez Canyon drainage. However, because the steepness of the arroyo created a sandy bed with very limited organics that would retain background naturally occurring radioactive material (NORM), it is believed that MTE-2 is a poor representation of the remainder of the drainage.

An aerial map is attached depicting the sample locations. The soil sample locations are also attached in Table 2 (below) with their respective New Mexico State Plane Coordinates and sample analysis results. See also Table 3.

The following observations are made based on the radionuclide data in Table 2:

- There appears to be no discernible dispersal of uranium and uranium progeny off the mine property.

- The concentrations of radionuclides in the Marquez Canyon arroyo adjacent and below Pond 8 (MTE-3, MTE-4, MTE-5, MTE-6) are equivalent to or lower than the background concentrations (MTE-1, MTE-2, MTE-7), indicating: 1) no discernible spread of contamination north of the current boundary; and 2) seasonal water flows purge organics from the Marquez arroyo thalweg that would contain naturally occurring radioactive material (NORM) and radionuclides from the mine (TENORM).

- Radionuclide concentrations in the alluvial deposits north and northeast of San Mateo (MTE-8, MTE-9, MTE-10, MTE-11, MTE-13, MTE-14) are consistent with NORM concentrations typical for this region at locales away from uranium mining operations. There are no identifiable patterns that would indicate the dispersal of uranium and radium into the plain from Mt. Taylor Mine.

- The slightly elevated ambient radiation readings north of Pond 8 were not explained by the soil sample analyses performed for this investigation. Please compare the survey results for MTE-3 and MTE-4 against the survey results for the background locations:

**Table 1**

| **Location** | **Dose Rate** µrem/h | **U-238** pCi/g | **Ra-226** pCi/g |
|---|---|---|---|
| MTE-1 (Surface Grade BKG) | 18 | 1.6 | 1.7 |
| MTE-7 (Surface Grade BKG) | 13 | 0.6 | 1.5 |
| MTE-3 (Surface Grade) | 26 | 0.5 | 1.4 |

Regressional analysis of the data in Table 2 indicates very poor statistical correlation between the dose rates and the concentrations of Radium-226 in the soil.

The conclusions are that: 1) radiation "shine" from nearby and elevated rock and soils could be affecting the instrument readings; and 2) soil sample analyses must be performed along with dose rate surveys when evaluating remediation requirements.

The analyses presented in this report were performed at Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Radiochemistry analyses were performed at Energy Laboratories, Inc., 2325 Kerzell Lane, Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

The results as reported relate only to the item(s) submitted for testing. Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. Data corrected for moisture content are typically noted as -dry on the report. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

If you have any questions regarding these test results, please call.

Report Approved By:

**CLIENT:** Rio Grande Resources Corporation
**Project:** Mt. Taylor Mine
**Sample Delivery Group:** C12041338

**Report Date:** 06/01/12

# CASE NARRATIVE

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

ACZ Project ID: L43559

Alan Kuhn:

Enclosed are the analytical results for sample(s) submitted to ACZ Laboratories, Inc. (ACZ) on April 05, 2018. This project has been assigned to ACZ's project number, L43559. Please reference this number in all future inquiries.

All analyses were performed according to ACZ's Quality Assurance Plan. The enclosed results relate only to the samples received under L43559. Each section of this report has been reviewed and approved by the appropriate Laboratory Supervisor, or a qualified substitute.

Except as noted, the test results for the methods and parameters listed on ACZ's current NELAC certificate letter (#ACZ) meet all requirements of NELAC.

This report shall be used or copied only in its entirety. ACZ is not responsible for the consequences arising from the use of a partial report.

All samples and sub-samples associated with this project will be disposed of after May 30, 2018. If the samples are determined to be hazardous, additional charges apply for disposal (typically $11/sample). If you would like the samples to be held longer than ACZ's stated policy or to be returned, please contact your Project Manager or Customer Service Representative for further details and associated costs. ACZ retains analytical raw data reports for ten years.

If you have any questions or other needs, please contact your Project Manager.

S. Habermehl

Scott Habermehl has reviewed
and approved this report.

## Report Header Explanations

| | |
|---|---|
| *Batch* | A distinct set of samples analyzed at a specific time |
| *Found* | Value of the QC Type of interest |
| *Limit* | Upper limit for RPD, in %. |
| *Lower* | Lower Recovery Limit, in % (except for LCSS, mg/Kg) |
| *MDL* | Method Detection Limit. Same as Minimum Reporting Limit unless omitted or equal to the PQL (see comment #5). Allows for instrument and annual fluctuations. |
| *PCN/SCN* | A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis |
| *PQL* | Practical Quantitation Limit. Synonymous with the EPA term "minimum level". |
| *QC* | True Value of the Control Sample or the amount added to the Spike |
| *Rec* | Recovered amount of the true value or spike added, in % (except for LCSS, mg/Kg) |
| *RPD* | Relative Percent Difference, calculation used for Duplicate QC Types |
| *Upper* | Upper Recovery Limit, in % (except for LCSS, mg/Kg) |
| *Sample* | Value of the Sample of interest |

## QC Sample Types

| | | | |
|---|---|---|---|
| *AS* | Analytical Spike (Post Digestion) | *LCSWD* | Laboratory Control Sample - Water Duplicate |
| *ASD* | Analytical Spike (Post Digestion) Duplicate | *LFB* | Laboratory Fortified Blank |
| *CCB* | Continuing Calibration Blank | *LFM* | Laboratory Fortified Matrix |
| *CCV* | Continuing Calibration Verification standard | *LFMD* | Laboratory Fortified Matrix Duplicate |
| *DUP* | Sample Duplicate | *LRB* | Laboratory Reagent Blank |
| *ICB* | Initial Calibration Blank | *MS* | Matrix Spike |
| *ICV* | Initial Calibration Verification standard | *MSD* | Matrix Spike Duplicate |
| *ICSAB* | Inter-element Correction Standard - A plus B solutions | *PBS* | Prep Blank - Soil |
| *LCSS* | Laboratory Control Sample - Soil | *PBW* | Prep Blank - Water |
| *LCSSD* | Laboratory Control Sample - Soil Duplicate | *PQV* | Practical Quantitation Verification standard |
| *LCSW* | Laboratory Control Sample - Water | *SDL* | Serial Dilution |

## QC Sample Type Explanations

| | |
|---|---|
| Blanks | Verifies that there is no or minimal contamination in the prep method or calibration procedure. |
| Control Samples | Verifies the accuracy of the method, including the prep procedure. |
| Duplicates | Verifies the precision of the instrument and/or method. |
| Spikes/Fortified Matrix | Determines sample matrix interferences, if any. |
| Standard | Verifies the validity of the calibration. |

## ACZ Qualifiers (Qual)

| | |
|---|---|
| B | Analyte concentration detected at a value between MDL and PQL. The associated value is an estimated quantity. |
| H | Analysis exceeded method hold time. pH is a field test with an immediate hold time. |
| L | Target analyte response was below the laboratory defined negative threshold. |
| U | The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit. |

## Method References

## Comments

| | |
|---|---|
| (1) | QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations. |
| (2) | Soil, Sludge, and Plant matrices for Inorganic analyses are reported on a dry weight basis. |
| (3) | Animal matrices for Inorganic analyses are reported on an "as received" basis. |
| (4) | An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result. |
| (5) | If the MDL equals the PQL or the MDL column is omitted, the PQL is the reporting limit. |

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

## Report Header Explanations

| | |
|---|---|
| *Batch* | A distinct set of samples analyzed at a specific time |
| *Error(+/-)* | Calculated sample specific uncertainty |
| *Found* | Value of the QC Type of interest |
| *Limit* | Upper limit for RPD, in %. |
| *LCL* | Lower Control Limit, in % (except for LCSS, mg/Kg) |
| *LLD* | Calculated sample specific Lower Limit of Detection |
| *PCN/SCN* | A number assigned to reagents/standards to trace to the manufacturer's certificate of analysis |
| *PQL* | Practical Quantitation Limit |
| *QC* | True Value of the Control Sample or the amount added to the Spike |
| *Rec* | Amount of the true value or spike added recovered, in % (except for LCSS, mg/Kg) |
| *RER* | Relative Error Ratio, calculation used for Dup. QC taking into account the error factor. |
| *RPD* | Relative Percent Difference, calculation used for Duplicate QC Types |
| *UCL* | Upper Control Limit, in % (except for LCSS, mg/Kg) |
| *Sample* | Value of the Sample of interest |

## QC Sample Types

| | | | |
|---|---|---|---|
| *DUP* | Sample Duplicate | *MS/MSD* | Matrix Spike/Matrix Spike Duplicate |
| *LCSS* | Laboratory Control Sample - Soil | *PBS* | Prep Blank - Soil |
| *LCSW* | Laboratory Control Sample - Water | *PBW* | Prep Blank - Water |

## QC Sample Type Explanations

| | |
|---|---|
| Blanks | Verifies that there is no or minimal contamination in the prep method procedure. |
| Control Samples | Verifies the accuracy of the method, including the prep procedure. |
| Duplicates | Verifies the precision of the instrument and/or method. |
| Matrix Spikes | Determines sample matrix interferences, if any. |

## ACZ Qualifiers (Qual)

| | |
|---|---|
| H | Analysis exceeded method hold time. |

## Method Prefix Reference

| | |
|---|---|
| M | EPA methodology, including those under SDWA, CWA, and RCRA |
| SM | Standard Methods for the Examination of Water and Wastewater. |
| D | ASTM |
| RP | DOE |
| ESM | DOE/ESM |

## Comments

| | |
|---|---|
| (1) | Solid matrices are reported on a dry weight basis. |
| (2) | Preparation method: "Method" indicates preparation defined in analytical method. |
| (3) | QC results calculated from raw data. Results may vary slightly if the rounded values are used in the calculations. |
| (4) | An asterisk in the "XQ" column indicates there is an extended qualifier and/or certification qualifier associated with the result. |

For a complete list of ACZ's Extended Qualifiers, please click: http://www.acz.com/public/extquallist.pdf

|---|---|
| Radium 228, 3050 | M904.0 |

Soil Analysis

**The following parameters are not offered for certification or are not covered by NELAC certificate #ACZ.**

| | |
|---|---|
| Solids, Percent | D2216-80 |

ACZ Laboratories, Inc.
2773 Downhill Drive Steamboat Springs, CO 80487 (800) 334-5493

# Sample Receipt

**Alan Kuhn Associates LLC**
AKA-ACZ-2018.1

ACZ Project ID: L43559
Date Received: 04/05/2018 10:42
Received By:
Date Printed: 4/6/2018

## Receipt Verification

| | YES | NO | NA |
|---|---|---|---|
| 1) Is a foreign soil permit included for applicable samples? | | | X |
| 2) Is the Chain of Custody form or other directive shipping papers present? | X | | |
| 3) Does this project require special handling procedures such as CLP protocol? | | X | |
| 4) Are any samples NRC licensable material? | | | X |
| 5) If samples are received past hold time, proceed with requested short hold time analyses? | X | | |
| 6) Is the Chain of Custody form complete and accurate? | X | | |
| 7) Were any changes made to the Chain of Custody form prior to ACZ receiving the samples? | X | | |

A change was made in the Page 1 Sampler's Name. Relinquished By. Page 2 Copy of Report to. Invoice to. Relinquished By Date:Time section prior to ACZ custody.

## Samples/Containers

| | YES | NO | NA |
|---|---|---|---|
| 8) Are all containers intact and with no leaks? | X | | |
| 9) Are all labels on containers and are they intact and legible? | X | | |
| 10) Do the sample labels and Chain of Custody form match for Sample ID, Date, and Time? | X | | |
| 11) For preserved bottle types, was the pH checked and within limits? [1] | | | X |
| 12) Is there sufficient sample volume to perform all requested work? | X | | |
| 13) Is the custody seal intact on all containers? | | | X |
| 14) Are samples that require zero headspace acceptable? | | | X |
| 15) Are all sample containers appropriate for analytical requirements? | X | | |
| 16) Is there an Hg-1631 trip blank present? | | | X |
| 17) Is there a VOA trip blank present? | | | X |
| 18) Were all samples received within hold time? | X | | |

NA indicates Not Applicable

## Chain of Custody Related Remarks

The 'Relinquished By' field on the COC was not completed. The project manager is contacting the client.

ACZ Project ID: L43559
Date Received: 04/05/2018 10:42
Received By:
Date Printed: 4/6/2018

Was ice present in the shipment container(s)?

No - Wet or gel ice was not present in the shipment container(s).

Client must contact an ACZ Project Manager if analysis should not proceed for samples received outside of their thermal preservation acceptance criteria.

[1] The preservation of the following bottle types is not checked at sample receipt: Orange (oil and grease), Purple (total cyanide), Pink (dissolved cyanide), Brown (arsenic speciation), Sterile (fecal coliform), EDTA (sulfite), HCl preserved vial (organics), Na2S2O3 preserved vial (organics), and HG-1631 (total/dissolved mercury by method 1631).

| TECHNICAL MEMORANDUM | |
|---|---|
| **To**: Bruce Norquist (RGR) | **Date**: July 06, 2020 |
| **From**: Randy Whicker (ERG) | **Project**: Mt. Taylor Mine |
| **Direct**: 970-556-1174 | **Task(s)**: Site closeout/closure Support |
| **Cc**: Chuck Farr (ERG) | |
| **Subject**: Radiological survey results for discharge pipeline and soils along pipeline corridor. | |

Dear Mr. Norquist,

This Technical Memorandum provides the results of radiological surveys of the discharge pipeline and underlying/adjacent soils at the Rio Grande Resources (RGR) Mt. Taylor Mine near San Mateo, New Mexico. This work was conducted June 23-24, 2020 to support mine closeout/closure activities.

Please let me know if you have questions or need more information.

Regards,

*Randy Whicker, CHP*
*Radiation Safety Officer*
*Mt. Taylor Mine*

## 1. INTRODUCTION

The Mt. Taylor Mine (Site) is a former underground uranium mine in Cibola County near the town of San Mateo, New Mexico. Owned and operated by Rio Grande Resources (RGR), the Site is situated at the foot of Mount Taylor, an extinct volcano. Gulf Mineral Resources Company (Gulf) acquired the property and began mine development in 1971. Ore production occurred between 1979 – 1982, and after a transfer of ownership to Chevron Resources Company (Chevron) in 1985, production resumed through 1990. RGR acquired the mine and other Chevron property in 1991. In 1999 the Mine entered standby status under Mine Permit C1002RE with MMD. On December 29, 2017, the permit changed to an active status, and on December 3, 2019, RGR notified MMD of intentions to begin the Site closeout/closure process.

Discharge permit DP-61 with the New Mexico Environment Department (NMED) was first issued to Gulf in 1979. Mine water was treated to meet applicable water quality standards prior to conveyance through a pipeline and surface discharge at Outfall 001 located 4.3 miles north of the Site in San Lucas Canyon (Figure 1). RGR intends to dismantle and remove the pipeline and remediate any impacted soils along the pipeline corridor, along with impacted sediments at Outfall 001 in the San Lucas Canyon drainage.

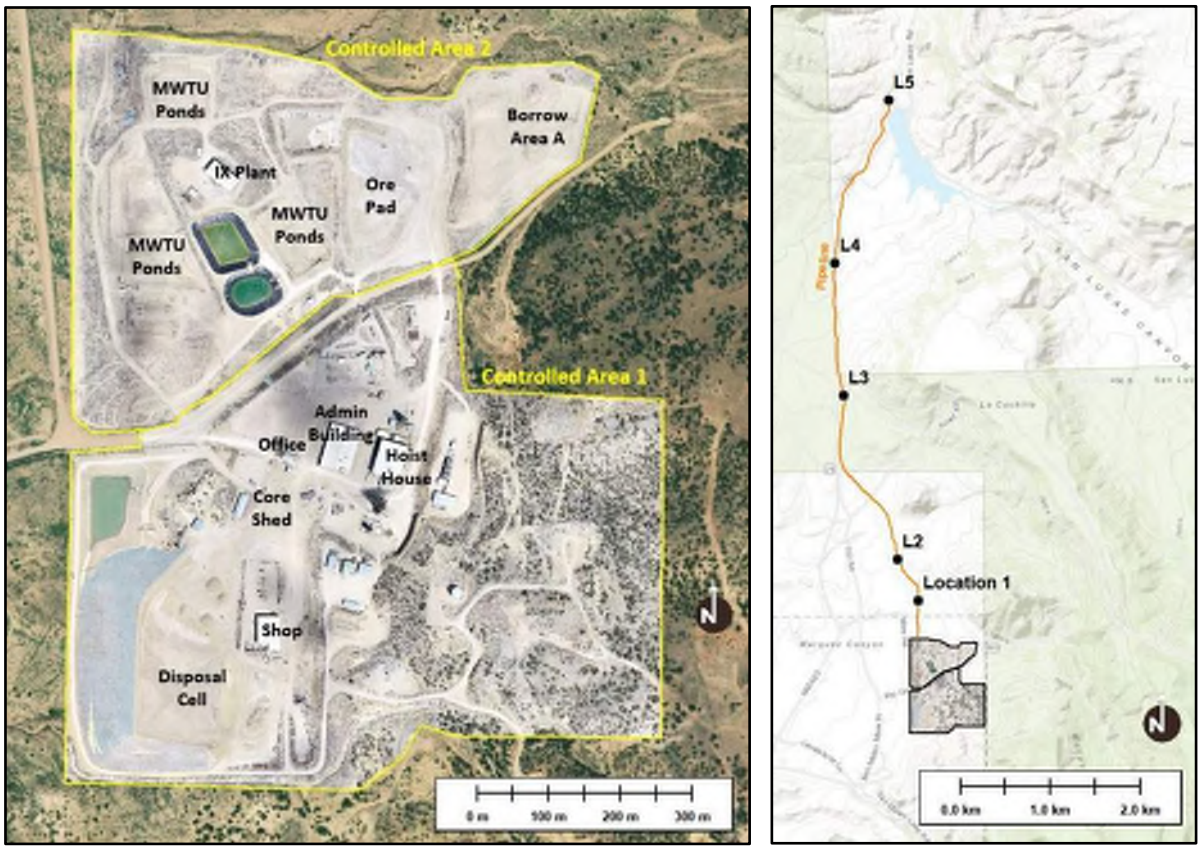

**Figure 1: Mine features within operationally Controlled Areas at the Site (left) and the 4.3 mile pipeline for conveyance of treated mine water for discharge at Outfall 001 in San Lucas Canyon under DP-61 (right). Locations for interior/exterior measurements of radiological properties of steel pipeline materials are also shown (right).**

Once dismantled and removed, the disposition of steel pipeline materials is dependent on the radiological condition of the material. The status of land areas along the pipeline corridor depends on the magnitude and extent of any radiological impacts to soils underlying and adjacent to the pipeline. This Technical Memorandum provides the results of radiological field screening measurements for pipeline materials (interior and exterior surfaces of steel piping material) at five (5) representative locations along the 4.3 mile length of the discharge pipeline (Figure 1), along with continuous GPS-based gamma scans adjacent to the pipeline to characterize terrestrial gamma radiation emissions from soils along the pipeline corridor.

Characterization survey results are presented in this report and values compared to applicable criteria for clearance or release from current radiological and regulatory controls on these mine-related features. The objective of these surveys was to help inform decisions on the future disposition of pipeline materials and infrastructure, and to estimate the extent of soil remediation that may be required along the pipeline corridor to meet Mine reclamation and closure objectives as specified in the *Mt. Taylor Mine Closeout/Closure Plan* (RGR, 2013).

## 2. CLEARANCE CRITERIA

### *2.1 Pipeline Materials and Equipment*

The clearance criteria for surface radioactivity levels on pipeline walls and volumetric criteria for loose sediments or scales are based on a national standard published jointly by the American National Standards Institute (ANSI) and the Health Physics Society (ANSI/HPS, 2013). More stringent than the U.S. Nuclear Regulatory Commission's criteria for unrestricted release of materials and equipment (M/E) from uranium recovery facilities (NRC, 2002), the ANSI/HPS standard is designed to protect human health by limiting potential radiological doses from future use of the M/E to a de-minimis value of 1 millirem (mrem)/year.

Clearance in the ANSI/HPS standard is defined as "the removal of items or materials that contain or *may* contain residual levels of radioactive materials within authorized practices from further radiological control for radiation protection purposes." This standard applies to the clearance of M/E from areas controlled to protect individuals from exposure to radiation or radioactive material during or after operations. This dose-based standard provides derived screening levels for surface and volume radioactivity. The derived screening levels that apply are presented in Table 1.

**Table 1: Surface activity screening levels for clearance of materials and equipment (adapted from ANSI/HPS, 2013).**

| Radionuclide Group | Surface Activity Limit | Volumetric Concentration Limit |
|---|---|---|
| *Group 1:* $^{Nat}$U, $^{Nat}$Th, and associated decay products: Pb210, Po210, Ra226, Ra228, Th228, Th230 | 600 dpm/100 $cm^2$ | 3 pCi/g |

The surface activity limit in Table 1 can be partitioned into alpha and beta components for the uranium and thorium decay series as follows:

The uranium decay series has 14 particles emitted, with 8 alphas (57%) and 6 betas (43%)
The thorium decay series has 12 particles emitted, with 7 alphas. (58%) and 5 betas (42%)

Since it is unknown what mixture of primordial decay series radionuclides may be present in any surface contamination on M/E at the Site, it is conservative to assume that all alpha emissions are from uranium decay series radionuclides only and an equivalent alpha screening level, assuming secular equilibrium between all uranium decay series radionuclides, is as follows:

600 dpm / 100 $cm^2$ * (0.57 α dpm/total dpm) ≈ **340 dpm α / 100 $cm^2$**

A similar calculation for beta activity gives a conservative beta screening level of 252 dpm β / 100 $cm^2$, a value that is well below the minimum detectable activity (MDA) achievable with a one-minute static count (the count time needed to meet an MDA of 250 dpm β / 100 $cm^2$ is on the order of 20-25 minutes). Given the need for a screening level that is practical to measure in the field, a screening level for alpha activity of 340 dpm/100 $cm^2$ will be used as the primary criterion for determination of compliance with the total surface activity clearance limit given in Table 1. In addition, a maximum alpha reading equivalent to 10 times the screening level (3,400 dpm α / 100 $cm^2$) for any single measurement (a secondary "hotspot" criterion) will be applied for consistency with related specifications in the ANSI/HPS standard. Individual items may be grouped into similar types of M/E to represent a "survey unit", and alpha readings within each survey unit may be used to determine compliance with both the average and hotspot alpha screening levels.

Because the ANSI clearance criteria in Table 1 were derived from a conservative receptor dose assessment that assumed infinite plane source term conditions (ANSI/HPS, 1999; Annex B), the averaging approach described above is consistent with regulatory guidance for comparison against clearance criteria as provided in MARSAME, the *Multi-Agency Radiation Survey and Assessment of Materials and Equipment Manual* (NRC, 2009). In other words, if a receptor were exposed to all M/E within a survey unit where average and maximum surface alpha activities are below respective alpha screening levels, the potential radiological dose to a receptor is conservatively assumed to be less than the de-minimis 1 mrem/year radiation dose limit specified in the ANSI/HPS standard.

If the average for the survey unit is below the primary alpha screening level, and no single measurement is greater than the secondary alpha hotspot criterion, then all M/E within the survey unit can be released from further radiological controls on the future disposition of the M/E. These criteria do not apply to offsite disposal as commercial disposal facilities may have their own radiological acceptance criteria and approved characterization methods for waste profiling. Pipeline materials that do not meet these clearance criteria will be flagged for either decontamination efforts, or for onsite disposal in the engineered waste disposal cell or offsite at an approved industrial waste disposal facility.

## *2.2 Pipeline Corridor and Outfall Soils/Sediments*

With respect to land areas along the pipeline corridor and the San Lucas Canyon drainage below discharge Outfall 001, the release criterion for surface soil or sediment (0-15 cm) is equivalent to a Ra-226 concentration of 5 pCi/g above background based on the "*Joint Guidance for the Cleanup and Reclamation*

*of Existing Uranium Mining Operations in New Mexico*" from the Mining and Minerals Division (MMD) and the Mining Environmental and Compliance Section of the New Mexico Environment Department (NMED) (MMD/NMED, 2016). The approved background Ra-226 concentration for the Site is 1.8 pCi/g, giving a total (gross) release criterion of 6.8 pCi/g of Ra-226. In addition, the "*Joint Guidance*" from MMD/NMED describes an additional criterion for ambient gamma radiation called the "post reclamation radiation level" (PRRL). As determined in RGR's "*Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands Mount Taylor Mine*" (RGR, 2020a), the PRRL for the Mount Taylor Site is equivalent to a gamma exposure rate of 24.5 micro-roentgen per hour (µR/hr). If surface soils along the pipeline corridor or sediments at Outfall 001 have Ra-226 concentrations below 6.8 pCi/g, and ambient gamma exposure rates are below 24.5 µR/hr, respective land areas can be released for the Post-Mining Land Use (PMLU) as described in the *Joint Guidance* (MMD/NMED, 2016). Otherwise, soil excavation will be required until these release criteria are achieved.

## 3. METHODS

The methods used for the radiological characterization measurements and gamma surveys along the pipeline were based on applicable standard operating procedures (SOPs) provided in the Radiation Protection Program (RPP) Manual for the Mt. Taylor Mine (RGR, 2020b), including:

- SOP-2: Instrument Testing and Calibration
- SOP-3: Radiological Contamination Surveys
- SOP-7: GPS-based Gamma Radiation Surveys
- SOP-8: Soil Sampling for Radiometric Analysis

Total alpha and beta surface radioactivity levels were measured on June 24, 2020 at multiple systematic locations (top, bottom and sides) both inside and outside accessible portions of the pipeline walls at each of the locations shown in Figure 1. In order to access the interior of the pipeline at each location, a welding torch was used to cut a hole through the steel pipeline walls approximately 2 feet in diameter. Swipe (smear) samples were collected at each measurement location to evaluate readily removable surface activity. Gamma exposure rates were also measured inside of the pipeline (center and bottom). Samples of scale/sediment accumulated in the bottom of the pipeline were sampled, then screened onsite to estimate Ra-226 levels based on gross gamma readings inside of a lead-shielded, low-background counting well. These samples were then sent offsite to a qualified commercial laboratory for quantitative determination of U-nat, Th-230, Ra-226, and Pb-210 concentrations.

All field measurement data were recorded in the field logbook. Swipe samples for removable surface activity were measured in the radiation control office and recorded. Instrument quality control (QC) measurements were taken and documented to ensure proper instrument function. Photos were taken of the interior/exterior of the pipeline at each sampling/measurement location. GPS-based gamma transects were walked parallel to the pipeline just adjacent to the pipe and about 5 meters away from the pipeline. Gamma readings were manually monitored while scanning, and locations with evidence of elevated readings (above apparent background) were investigated further with additional scans to identify the outer bounds of potential radiological impacts to soil related to the pipeline.

## 4. PIPELINE MATERIALS SURVEY RESULTS

The results of alpha/beta surface activity and gamma emission measurements, along with sampling of loose residual solids (scale/sediments) inside the pipeline, are presented in the following Subsections for the five representative pipeline survey locations shown in Figure 1.

### *4.1 Pipeline Location 1*

**Table 2A: Alpha/beta surface activity measurement results for pipeline survey Location 1.**

| Pipeline Location 1 | Total Alpha Activity (DPM/100 cm²) | Total Beta Activity (DPM/100 cm²) | Removable Alpha Activity (DPM/100 cm²) | Removable Beta Activity (DPM/100 cm²) |
|---|---|---|---|---|
| Clearance Criterion | 340 | 252 | N/A* | N/A* |
| Ambient Background | 2 | 345 | 0 | 92 |

## 5. PIPELINE CORRIDOR GAMMA SURVEY RESULTS

The gamma survey of the pipeline corridor indicates that the vast majority of soils underlying and adjacent to the discharge pipeline have terrestrial gamma emissions consistent with local background conditions (Figure 2). Approximately 7 small, localized areas of elevated gamma radiation, indicative of radiological impacts to surface soils due to historic pipeline operations, are present at various discrete locations along the corridor as depicted by the white boxes in Figure 2. Gamma exposure rate readings for six of these small "hotspots" are shown in closer detail in the insets to Figure 2. These results suggest that the volume of contaminated soil that may require excavation and removal to release pipeline corridor lands to the PRLU as described in the Mine Closeout/Closure Plan (RGR, 2013), is likely to be relatively small, perhaps a few tens to a few hundreds of cubic yards of material that may be contaminated in excess of the 6.8 pCi/g release criterion for Ra-226 concentrations in soil.

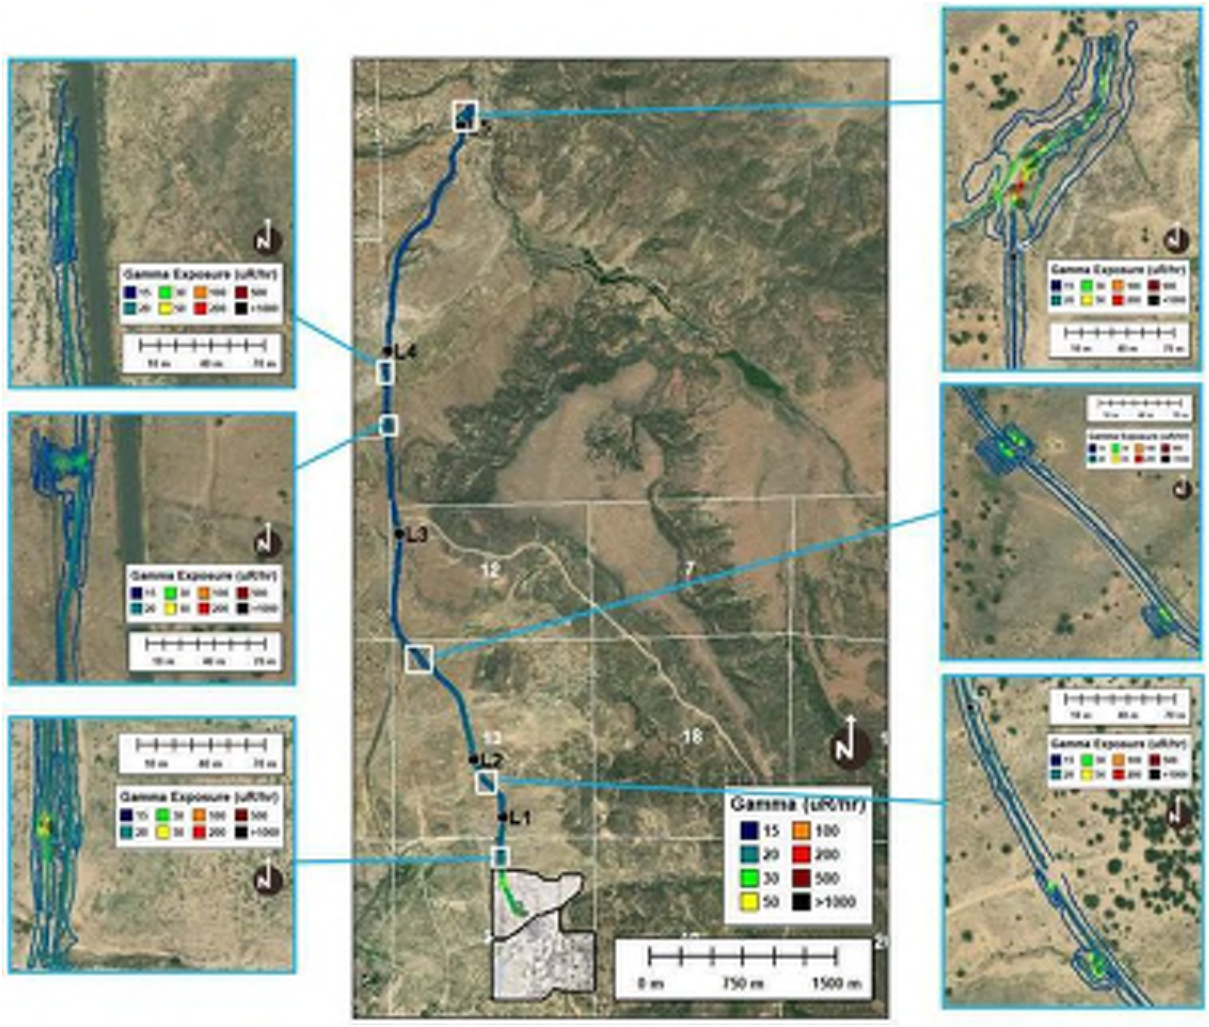

**Figure 2: Gamma survey results with detail insets to identify areas of small, localized hotspots that may require some relatively minor soil cleanup to meet the radiological criteria for release to the post remediation land use (PRLU).**

## 6. CONCLUSIONS

The results of the pipeline materials surveys (Section 4) indicate that in general, radiological impacts to the steel pipe along the length of the pipeline corridor exceed conservative, ANSI/HPS criteria for clearance from future radiological controls on access or reuse. Therefore, the options for future disposition of the pipeline materials are currently limited to 1) decontamination until the release criteria are met, or 2) onsite disposal in the engineered waste disposal cell or offsite disposal at an appropriate industrial waste disposal facility.

With respect to radiological impacts to soils, the gamma survey data suggest that spills or leaks were limited and the extent of impacts to soil that may require remediation are relatively small, perhaps involving excavation and removal of a few tens to a few hundreds of cubic yards of material. Removal of these small hotspots should result in compliance with the radiological soil release criteria specified in Section 2 along the entire length of the pipeline (including impacted sediments in the San Lucas drainage below Outfall 001 under DP-61).

## 1.0 Introduction and Background

This report provides the results of the Soil Radiologic Characterization (SRC) that was conducted at the Mt. Taylor Mine (Site) in Cibola County, near San Mateo, New Mexico. This SRC was performed to evaluate the lateral and vertical extent of radiologic contamination exceeding the Site Radiation Cleanup Criteria (RCC) of 6.8 pCi/g Ra-226 to estimate radiologic impacted material volumes within three specified areas of the Site; the Windblown Area, Ore Pad Area and portions of the Mine Compound Area, also known as the "Service and Support area". The methods and procedures used were consistent with the June 2020 Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands (2020 Work Plan) and the applicable survey methods described in the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM, EPA 2000a). The RCC specified in the March 2016 *Joint Guidance for the Cleanup and Reclamation of Existing Uranium Mining Operations in New Mexico* (EMNRD, 2016) (2016 Guidance) by the Energy, Minerals & Natural Resources Department (EMNRD) and the New Mexico Environment Department (NMED) was used for the investigation level (IL). The Ra-226 cleanup criteria of 5.0 pCi/g above the background level in land averaged over 100 square meters in surface soil (top six inches) specified in the Joint Guidance is taken from the UMTRCA (40 CFR 192) regulation, which is based on an unrestricted land use exposure scenario. A 6.8 pCi/g Ra-226 IL (5.0 pCi/g plus 1.8 pCi/g background level) has been established for the Site.

The Site was an underground uranium mine located in Cibola County, near San Mateo, New Mexico. The mine was developed by Gulf Mineral Resources Company (Gulf) in the 1970s and ore production occurred from 1979 to 1982. Following transfer of Site to Chevron Resources Company in 1985, the ore production resumed and continued until 1990. Rio Grande Resources (RGR) acquired the Site in 1991. In 1999 the Site entered standby status under Mine Permit C1002RE with EMNRD. On December 29, 2017, the permit changed to an active status, and on December 3, 2019, RGR notified MMD of intentions to begin the Site closeout/closure process. The following sections describe the strategy, methods and procedures that were used and the results of the SRC conducted at the Site.

## 2.0 Previous Characterization

Surface gamma radiation surveys were performed periodically within operationally controlled areas of the Site to monitor changes in radiological conditions during a period of remedial excavations in the Mine Water Treatment Unit (MWTU) ponds, construction of the disposal cell and placement of contaminated mine materials, and gradual removal of ore from the ore stockpile. The most recent gamma survey prior to this characterization, conducted March 27, 2021, showed elevated gamma radiation levels in certain operational areas within the Controlled Area boundaries, including the three areas included in this SRC, the Windblown Area, Ore Pad Area and the Mine Compound Area. The survey results are summarized in The June 2020 Work Plan, and indicate surface soils in portions of the Windblown Area, the Mine Compound and the entire Ore Pad Area exceed the 6.8 pCi/g Ra-226 IL.

Additionally, a radiologic subsurface soil investigation was performed in a portion of the Mine Compound Area as part of the 2020 Diesel Investigation. The results are summarized in the Mount Taylor Mine, Diesel Release Investigation Report of Finding, April 2021, Ensero Solutions, Inc. (Ensero 2021). The soil borings sample results within the Mine Compound Area indicate Ra-226 levels exceeding the IL in subsurface soils ranging from a depth of ground surface to 10 feet below ground surface (bgs) in the area around the Production Shaft.

## 3.0 Objective of the Radiological Characterization

The Site is a former uranium mine, therefore the surface and subsurface soil is expected to be impacted by radionuclides associated with the uranium decay series, with Ra-226 being the primary Constituent of Concern (COC). The objective of this characterization is to evaluate Ra-226 contamination exceeding the Site IL of 6.8 pCi/g Ra-226 in surface and subsurface soils to estimate volumes of radiologic impacted material within the Windblown, Ore Pad and Mine Compound Areas.

## 4.0 Field Investigation

Field investigations for this characterization were conducted consistent with the 2020 Work Plan and were conducted during the period of April 11, 2023 through June 14, 2023. The three specified soil characterization areas are shown in Figure 1. The field investigations included, both static 0.5 inch thick lead (Pb) collimated and uncollimated (bare) 2x2 sodium iodide (NaI) detector gamma radiologic survey measurements and Differential Global Positioning System (DGPS) based bare detector gamma scan surveys, along with ex-situ soil screening, soil sampling and offsite vendor laboratory analysis. The geo-located gamma scans were conducted to provide Ra-226 concentration level estimates in surface soil and to determine the test pit and sampling locations to assess subsurface radiologic contamination relative to the IL. Ex-situ gamma radiation soil screening was performed to provide real-time information to estimate subsurface contamination depths. Subsurface soil sampling and offsite vendor laboratory analysis was performed to confirm subsurface contamination depths below the IL as estimated by field ex-situ gamma radiation soil screening. Additionally, gamma radiation static surveys count per minute (cpm) measurements, exposure rate (µR/hr) measurements and surface soil samples and analysis were performed at selected locations to update the Site-specific correlation.

### 4.1 Surface Gamma Radiation Scan and Static Survey

The instrument configuration for direct gamma radiation level measurements during this characterization consisted of lead collimated and bare 2x2 NaI scintillation detectors (Eberline SPA-3 or Ludlum 44-10) for detection of gamma radiation, coupled to a scaler/rate meter (Ludlum 2221 or Ludlum 2241). This instrument configuration is used widely for this type of survey and is recommended by the MARSSIM. The scaler/rate meters were interfaced with a sub-meter accurate DGPS with surveying software and a data

logger/controller for electronically recording the gamma radiation levels to the corresponding geo-location coordinates. The coordinate system that was used for this work was the State Plane Coordinate System (NAD83, New Mexico West, US Feet) system. Direct gamma radiation surveys using a NaI scintillation detector provide radiation levels in counts per unit time, generally obtained as cpm. A Ludlum Model 19 µR Meter was used for gamma exposure rate (µR/hr) measurements.

During this characterization, systematic gamma radiation scan surveys using bare 2x2 NaI detectors were performed at the Site to determine the level of Ra-226 in surface soil within the characterization areas. Although bare detectors do not avoid lateral gamma radiation shine, bare detectors have a large field of view and provide a large scan coverage area for an efficient and conservative lateral extent of contamination assessment. The gamma scan surveys were performed consistent with the 2020 Work Plan. Thirty-feet spaced geo-projected transects for each area were digitally created using mapping software and loaded on the field data logger/controller. Based on a conservative field of view (FOV) of at least six feet diameter for a bare 2x2 NaI detector for Ra-226 gamma radiations, a scanning transects spacing of 30 feet would provide at least a 20% scan coverage. The gamma scan survey was performed by scanning along these transects with a bare 2x2 NaI detector at 12 inches above the ground surface at a scan rate of about three feet per second, with a data collection time interval of two seconds.

The geo-located gamma scan data includes the gamma scan point ID, date and time, location coordinates, and bare detector gamma cpm. The scan data was exported from the data logger and the bare detector cpm were converted to equivalent Ra-226 estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0005 x CPM)-7.3228 $R^2$ = 0.97)(2020 Work Plan). The scan data was mapped using a mapping software, arranged in color coded ranges and then reviewed to identify areas that exceeded the IL. The color-coded range was structured to include the Ra-226 6.8 pCi/g IL as shown in Figures 2 and 3. The characterization gamma scan survey included approximately 12,107 gamma scan data points within a total of approximately 40 acres at the Site. The gamma scan data was exported from the scan system data logger into an Excel file. The detector cpm was converted into equivalent estimated surface soil Ra-226 concentration in pCi/g using the Site-specific correlation for bare detectors as discussed in Section 4.5 of the 2020 Work Plan. A typical gamma scan data export table from the scan system data logger is shown in Table 1. Gamma scan survey data for this characterization are provided in electronic file.

One-minute static gamma radiation surveys were performed prior to collecting a soil sample at each surface soil sampling and test pit location using a bare 2x2 NaI detector and collimated 2x2 NaI detector. The survey data were recorded on Static Gamma Radiation Survey Forms, which are included in Appendix A. The bare detector cpm data was converted to equivalent Ra-226 estimate using the Site-specific correlation. A site-specific correlation for a 2x2 NaI 0.5-inch thick lead collimated detector was developed using the surface (0 – 6 Inch) soil samples collected from the Windblown Area and the co-located collimated detector survey performed during this characterization, which is included in Appendix C. This correlation regression yielded an equation of Ra=226 = (CPM x 0.0016) – 8.41 with an acceptable $R^2$ value

of 0.83 The collimated detector measurements were converted to soil Ra-226 concentrations using this correlation equation. The static gamma survey results are summarized in Table 2.

### 4.2 Ra-226 Radiation Cleanup Criteria Contamination Boundary

The Windblown area Ra-226 6.8 pCi/g RCC contamination boundary delineated based on the surface gamma scan survey and a 6.8 pCi/g Ra-226 RCC contamination boundary based on the surface soil sample ex-situ screening and vendor laboratory results are shown in Figure 4. The ex-situ and vendor lab Ra-226 pCi/g surface soil sample results are lower than the Ra-226 pCi/g concentrations estimated by the bare 2x2 NaI detector surface soil gamma scan. Based on the results of the soil sample analysis and static gamma radiation surveys, the area of the Windblown Area that exceeds the IL is smaller than previously estimated by bare detector gamma scan surveys alone, as shown in Figure 4. The primary cause of the overestimated Ra-226 concentrations in the Windblown Area determined by the bare detector gamma scan survey appears to be the lateral gamma radiation shine interference from nearby areas with elevated Ra-226 concentrations, specifically the close proximity to the Ore Pad Area. As discussed previously, one-minute static gamma radiation level measurements were performed prior to collecting a soil sample at each location using a bare and a 0.5 inch lead collimated 2x2 NaI detector. As shown in Tables 2 and 3, the Ra-226 concentration estimates determined using the collimated detector are comparable to the on-Site ex-situ gamma screening and the vendor laboratory Ra-226 analytical results. Thus, delineation of the Windblown Area surface soils exceeding the 6.8 pCi/g Ra-226 IL using the collimated static gamma survey, the on-Site ex-situ gamma screening and the vendor laboratory Ra-226 analytical results are appropriate, as shown in Figure 4.

As shown in Tables 2 and 4, and Figure 2 the entire Ore Pad Area surface soil far exceeds the 6.8 pCi/g Ra-226 IL. Additionally, surface soil gamma scans previously performed in 2018 and 2020 (2020 Work Plan) for area exposure rates (µR/hr) included the Mine Compound Area and showed that the majority of the Mine Compound Area exceeds the IL. As shown in Figure 3, the surface gamma scan performed during this characterization also shows that the surface soil in the majority of the Mine Compound Area exceeds the 6.8 pCi/g Ra-226 IL. To better characterize the surface soil and to assist in the selection of test pit locations, the surface gamma scan survey was performed at a higher density, 30-feet transect spacing, compared to the previous scan (2021) density of 60-ft transect spacing.

### 4.3 Test Pits, Soil Sampling and Ex-Situ Gamma Radiation Soil Screening

Test pit trench excavations, subsurface soil sampling and on-Site ex-situ gamma radiation soil screening were performed from May 17 through June 7, 2023. These methods were used to determine the subsurface soil Ra-226 contamination depth exceeding the IL at the test pit locations within the three characterization areas. The ex-situ gamma radiation soil screening was conducted to provide a real-time estimate of Ra-226 concentrations in subsurface soil samples. This method is more reliable than the in-situ

direct gamma radiation level measurements and allows for real-time Ra-226 concentration assessments. The on-Site ex-situ soil screening method consists of selectively measuring the 609 KeV region gamma radiations of Bi-214, a decay product of Ra-226. A single channel analyzer (Ludlum L2221) integrated with a Ludlum 44-20 3x3 NaI scintillation detector was used to measure the 609 keV energy peak region of Bi-214. The soil sample was placed around the plastic lined detector in a heavily lead shielded counting chamber. The heavily shielded counting chamber lowers the system background counts, thus improving the system's minimum detectable concentration (MDC). A reference soil with the Ra-226 concentration of 6.6 pCi/g, comparable to the 6.8 pCi/g IL, was prepared as described in Appendix C and was used for soil screening during this characterization. The 6.6 pCi/g reference soil provides a conservative estimate of Ra-226 concentration in samples below the IL.

A total of 12 locations were selected in the Windblown Area for surface and subsurface soil sampling in areas that exceeded the IL determined by the surface soil gamma scan survey, as shown in Figure 2. Twenty-eight test pit locations were selected for subsurface soil sampling based on the surface soil gamma scan survey and Site operational history where Ra-226 contamination was likely to be deeper than one-foot bgs, twenty test pits in the Mine Compound Area and eight in the Ore Pad Area, as shown in Figures 2 and 3.

Hand augers and sampling trowels were used to collect surface and subsurface soil samples up to a depth of 1.5 feet in the Windblown Area. At each of the 11 sample locations selected in the Windblown Area, a surface (0 – 6”) and a subsurface (1’ – 1.5’) soil sample were collected. At one location, a sample was collected at 0-1” and 2"-6” depths for surface soils Ra-226 contamination distribution analysis. A backhoe was used to excavate a trench at each selected test pit location for subsurface soil sample collection in the Ore Pad and Mine Compound areas. The trenches were excavated at approximately one-to-two-foot depth intervals depending on visual observations of the type and consistency of the soil. At each interval, a subsurface soil sample was collected from the base of the excavation for ex-situ soil screening. The excavation continued at least 2 feet after native soil was observed and on-Site ex-situ soil screening indicated Ra-226 concentrations were below the 6.8 pCi/g IL. The test pit excavation soil sample logs and the field soil screening forms are included in Appendix B. The test pit subsurface soil ex-situ gamma screening data is summarized in Tables 3, 4 and 5, which includes Ra-226 concentrations of the samples relative to the 6.8 pCi/g IL.

Although the primary objective of the ex-situ gamma radiation soil screening was to determine the Ra-226 concentrations above or below the 6.8 pCi/g IL, Ra-226 concentrations were estimated in all test pit excavation subsurface soil samples collected and screened. During the setup of the soil screening system prior to mobilizing in the field, a calibration/correlation of the ex-situ soil screening system was performed using a 6.6 pCi/g, a 25 pCi/g and a 50 pCi/g reference soil. This correlation is included in Appendix C. The estimated Ra-226 concentration of the subsurface soil samples determined using this correlation are included in Tables 3, 4 and 5.

Fourteen samples out of a total of 24 surface and subsurface soil samples screened on-Site from the Windblown Area were sent to the off-Site vendor laboratory, Energy Laboratories, in Casper, WY. From the Ore Pad and Mine Compound Areas, 34 samples out of a total of 88 subsurface soil samples screened onsite were sent to the off-site vendor laboratory. These soil samples were analyzed for Ra-226 using EPA Method 901.1 (modified for soil matrix) for confirmation of the on-Site ex-situ soil screening results. The 53 samples sent to the laboratory included at least one sample from each test pit excavation that screened below the IL. Also, 10% (5 samples) of the samples sent to the lab were split in the field and sent to the lab for quality assurance/quality control (QA/QC) duplicates. The laboratory results reports are included in Appendix B and are summarized in Table 3, 4 and 5. As shown in these tables, the estimated Ra-226 levels by on-Site ex-situ soil screening are comparable with the laboratory Ra-226 results, specifically in regard to determining the depth of Ra-226 levels above or below the IL.

### 4.4 Windblown Area Characterization Summary

As shown in Table 3 and Table 6, 11 of the 12 surface soil (0 – 6”) samples from the Windblown Area screened on-Site and analyzed by the vendor laboratory show Ra-226 pCi/g below the 6.8 pCi/g IL. The only location above the IL was WBSB-08 at 9.7 pCi/g. The Ra-226 concentration in all of the Windblown Area subsurface samples screened on-Site and analyzed by the vendor laboratory show Ra-226 pCi/g concentrations below the Ra-226 6.8 pCi/g IL, which is far below the Ra-226 15 pCi/g 2016 Guidance for 6-inch soil layers six inches bgs. This demonstrates that the Ra-226 levels exceeding the IL are contained only within the surface soil (0 – 6”) in the Windblown area, as shown in Figure 4 and Table 3. Furthermore, analyzing the 0-1” and 2”-6” soil samples resulted in Ra-226 concentrations of 2.0 pCi/g in the 0-1” sample and 1.0 pCi/g in the 2”-6” sample. Based upon the lab results in the Windblown area, the majority of the contamination is distributed within the top one inch of soil.

### 4.5 Ore Pad Area Characterization Summary

Results of test pit excavation observations and subsurface soil sampling analysis in the Ore Pad Area show waste rock depth from surface level to the native soil at approximately three to five feet bgs at four (OPSB-02, OPSB-03, OPSB-04 and OPSB-05) out of the five selected test pit locations, as shown in Table 4 and 6. The on-Site ex-situ gamma screening results show Ra-226 concentrations ranging from about 22 to 510 pCi/g as shown in Table 4. At test pit location OPSB-01, waste rock was observed at depths greater than five feet. A thin dark clay layer was observed at about five feet bgs. Excavation continued as light gray waste rock material and debris was constantly observed to a depth of 13.5 feet bgs, the excavation depth limit of the trenching equipment. The on-Site ex-situ gamma screening results show a Ra-226 concentration in the 0 to 13 feet composite sample from this location at 74 pCi/g, and 31 pCi/g Ra-226 in the sample from a depth of 13.5 feet. Since waste rock depth at all other test pit locations in the Ore Pad Area was approximately four to five feet, three additional test pits were excavated east of OPSB-01 to determine the

extent of waste rock depth in the area. Test pit locations OPSB-06 and OPSB-07 were selected at approximately 150' and 100' east of OPSB-01, respectively. Both of these test pits showed waste rock depths of approximately 4' bgs before observing native soil. Test pit location OPSB-08 was selected approximately 62' east of OPSB-01 and showed a waste rock and debris depth similar to that of OPSB-01. According to Site operational history, a portion of the nearby treatment pond may have been backfilled with low grade waste rock and used as part of the foundation for the Ore Pad Area. The waste rock depth in the OPSB-01 area is estimated to be about 15 feet bgs based on the nearby ore-pad runoff retention pond depth.

### 4.6 Mine Compound Area Characterization Summary

Results of test pit excavation observations and subsurface soil sampling analysis in the Mine Compound Area show subsurface soil exceeding the 6.8 pCi/g Ra-226 IL at varying depths ranging from ground surface to about seven feet bgs as shown in Tables 5 and 6 and Figure 5. Soil exceeding the IL is generally limited to only the surface soil (<1.0 feet) in the areas around test pit locations MCSB-04, MCSB-10, MCSB-12, MCSB-13, MCSB-14, MCSB-15, MCSB-16, MCSB-17 and MCSB-18. At the other nine test pit locations, soil/ material depths bgs exceeding the IL are shown in Table 6, except at test pit locations MCSB-02 and MCSB-05. Test pits MCSB-02 and MCSB-05 had an isolated layer of soil/gravel that exceeded the IL while the soil above and below the layer screened below the IL. At test pit location MCSB-02, soil exceeding the IL was found in a gravel layer at a depth of 3.5 to 4.5 feet bgs, while at a depth of 5.5 to 6.5 feet bgs at test pit location MCSB-05, as shown in Tables 5 and 6, and Figure 5. At each test pit location, when native soil was observed, excavation continued into the native soil at least two feet to ensure that the soil/material exceeding the IL had been identified. Two additional observation test pit excavations up to nine feet were performed at locations MCSB-19 and MCSB-20. These two test pits are located east of locations MCSB-08 and MCSB-11, between the shop yard fence and the road. The purpose of these two observational test pit excavations was to estimate the lateral extent of subsurface waste rock material found at locations MCSB-08 and MCSB-11. Identification of any waste rock material was noted by visual observation. No waste rock material was observed in test pit MCSB-19, east of Test Pit MCSB-08. A thin (approximately 3") layer of waste rock material at a depth of 2.0 to 2.25' was observed in Test Pit MCSB-20, indicating that the lateral extent boundary of subsurface waste rock material is between MCSB-11 and the shop yard fence line. Based on the field soil screening and the laboratory sample results, depths of Ra-226 concentrations above the 6.8 pCi/g IL at each Ore Pad and Mine Compound Area test pit and Windblown Area sampling location are summarized in Table 6.

## 5.0 Soil Sampling and Analysis

Soil samples from the Windblown Area and subsurface soil samples from the test pit excavations collected for on-Site ex-situ gamma radiation soil screening were collected consistent with the 2020 Work Plan. Field QA/QC duplicate samples were split at a frequency of 10% of the total number of soil samples collected. A total of 112 surface and subsurface soil samples were collected during this characterization. Field sampling

equipment used for soil sampling included: stainless steel scoops, bowls, spoons, and hand auger barrels were decontaminated between sample locations. The soil sampling equipment decontamination was conducted by brushing off loose visible soil and wiped with clean towels. Excavator buckets were cleaned by removing any loose, visible soil. Any soils excavated from the test pits were returned to the test pit excavations from which the soil came. Personal protection equipment (PPE), such as gloves, were brushed off and scanned for residual contamination and were disposed of.

Surface and subsurface soil samples were analyzed by on-Site ex-situ gamma radiation soil screening (AVM SOP-4) to estimate Ra-226 concentrations. A completed Chain-of-Custody (COC) along with the surface soil samples and confirmatory soil samples were placed in labeled Ziploc bags, and packaged in coolers with sealed lids and shipped to Energy Laboratories, Inc for Ra-226 analysis. The soil samples were analyzed for Ra-226 with a reporting limit of 0.5 pCi/g, using EPA Method 901.1 (modified for soil matrix). The completed COCs are included with the analytical results reports in Appendix B.

## 6. 0 Quality Assurance and Quality Control Measures

QA/QC measures were implemented during this characterization to ensure that decisions were made based on data of acceptable quality. All radiologic survey instruments have been calibrated at least annually. Additionally, operational functions checks were performed on all radiologic instruments daily prior to use. The calibration and function check documents are included in Appendix C. During this characterization, no instruments were found to be out of calibration or inoperable as indicated by the operational function checks. The instrument background measurements for bare 2x2 NaI detectors during daily operational function checks were less than 10,000 cpm as shown in Appendix C. The bare detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of six feet diameter. The 2x2 NaI detector response factor is determined to be 0.0005 pCi/g/cpm from the linear regression for the Site-specific correlation included in Appendix C. Based on the above detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a scan survey at a scan speed of three feet per second, calculated using MARSSIM guidance, were less than 1.0 pCi/g, which is significantly less than 50% of the 6.8 pCi/g IL. The ex-situ soil gamma radiation screening system was calibrated prior to mobilization in the field and daily operational function checks were performed prior to use. The calibration and function check documentation are included in Appendix C. Based on the highest system background (blank) measurements from daily operational function checks and efficiency (pCi/g/cpm), the highest Ra-226 MDC for the screening system calculated was less than 0.8 pCi/g, significantly less than the 6.8 pCi/g IL. The MDCs during the supplemental characterization met the QA objective.

The QA/QC measures also included field QA/QC duplicate soil sampling at a frequency of 10% of the soil samples collected for laboratory analysis. As discussed above, field QA/QC duplicate soil samples were collected and sent to the laboratory for analysis, and the QA/QC duplicate results are included in appropriate summary tables.

Figure 5
Mt. Taylor Mine Site
Mine Compound Area Subsurface Soil Sample
On-Site Ex-Situ Soil Screening and Lab Results
and April 2023 Surface Gamma Scan Survey

**Legend**

**Ra-226 pCi/g**

- <1.8 pCi/g
- 1.9 - 6.8 pCi/g
- 6.9 - 10.0 pCi/g
- 10.1 - 20.0 pCi/g
- 20.1 - 30.0 pCi/g
- 30.1 - 40.0 pCi/g
- >40.1 pCi/g
- Soil Sample/Test Pit Location
- North Controlled Fence
- Soil Radiologic Characterization Area

Note: Ra-226 pCi/g is determined from surface soil gamma radiation scan using 2x2 NaI detector and Site specific gamma radiation level (cpm) correlation.

# ANALYTICAL SUMMARY REPORT

August 07, 2023

Rio Grande Resources Corporation
PO Box 1150
Grants, NM 87020-1150

Work Order: C23060688 Quote ID: C16056

Project Name: MTM Subsurface soil investigation

Energy Laboratories, Inc. Casper WY received the following 53 samples for Rio Grande Resources Corporation on 6/19/2023 for analysis.

| Lab ID | Client Sample ID | Collect Date | Receive Date | Matrix | Test |
|---|---|---|---|---|---|
| C23060688-001 | WBSB-02 0-6" | 05/17/23 8:15 | 06/19/23 | Soil | Gamma Sample Preparation Drying/Grinding, Radiochemistry Gross Gamma |

The analyses presented in this report were performed by Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the report package. Any issues encountered during sample receipt are documented in the Work Order Receipt Checklist.

The results as reported relate only to the item(s) submitted for testing. This report shall be used or copied only in its entirety. Energy Laboratories, Inc. is not responsible for the consequences arising from the use of a partial report.

If you have any questions regarding these test results, please contact your Project Manager .

Report Approved By:

**CLIENT:** Rio Grande Resources Corporation
**Project:** MTM Subsurface soil investigation
**Work Order:** C23060688

**Report Date:** 08/07/23

# CASE NARRATIVE

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

BRANCH LABORATORY LOCATIONS
eli-b - Energy Laboratories, Inc. - Billings, MT
eli-g - Energy Laboratories, Inc. - Gillette, WY
eli-h - Energy Laboratories, Inc. - Helena, MT

ISO 17025 DISCLAIMER:
The results of this Analytical Report relate only to the items submitted for analysis.

ENERGY LABORATORIES, INC. - CASPER,WY certifies that certain method selections contained in this report meet requirements as set forth by the above accrediting authorities. Some results requested by the client may not be covered under these certifications. All analysis data to be submitted for regulatory enforcement should be certified in the sample state of origin. Please verify ELI's certification coverage by visiting www.energylab.com

ELI appreciates the opportunity to provide you with this analytical service. For additional information and services visit our web page www.energylab.com.

| Water - pH acceptable upon receipt? | Yes ☐ | No ☐ | Not Applicable ☑ |

### Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

The reference date for Radon analysis is the sample collection date. The reference date for all other Radiochemical analyses is the analysis date. Radiochemical precision results represent a 2-sigma Total Measurement Uncertainty.

### Contact and Corrective Action Comments:

Energy Labs INC is missing pages three and four worth of samples from the chain of custody. All other samples are present and match the Chain of Custody.

We received the missing samples on 6/20/2023 @1000. The samples are intact and match the Chain of Custody. The Temperature for the cooler was 24.8°C and received with no temp blank or ice.
NOTE: The Lab Sample ID's will reflect a received date of when the initial samples were received which will be 6/19/2023 @1000.
Called and spoke with Ms.Anita and informed her we received the samples.

# Addendum

## August 14, 2023 Surface and Subsurface Soil Radiologic Characterization Report Windblown Area, Ore Pad Area and Mine Compound, Mount Taylor Mine Site

This addendum presents the revision to the Ore Pad soil radiologic characterization summary described in the August 14, 2023 Surface and Subsurface Soil Radiologic Characterization; Windblown Area, Ore Pad Area and Mine Compound Report (Report) for the Mt. Taylor Mine Site (Site). As discussed in Section 4.5 and shown in Figure 2 of the Report, the approximated depth of waste rock from ground surface to non-impacted native soil in the northwest area of the Ore Pad was estimated at 15 feet, two feet past the excavation depth limit of the trenching equipment, at two test pit locations (OPSB-01 and OPSB-08). The waste rock depth in the other areas of the Ore Pad ranged from 3.0 feet to 4.5 feet below ground surface (bgs). Upon review of historical operational information, the eastern portion of the adjacent Ore Pad Runoff Retention Pond (Retention Pond) was backfilled with low grade waste rock and used as part of the foundation for the Ore Pad Area expansion. A 1981 aerial image of the Site (Figure 1A) shows the footprint of the Retention Pond prior to backfilling to expand the Ore Pad. The 1981 aerial image explains the cause of the anomalous estimated depth of the waste rock in the northwest area of the Ore Pad compared to the remainder of the areas of the Ore Pad. As shown in Figure 2A, recent topographic contours show the elevation of the northwest area of the Ore Pad ground surface at 7320 feet mean sea level (msl) and the Retention Pond bottom ground surface at 7298 feet msl. Considering that the waste rock in the existing Retention Pond is two feet thick, the baseline elevation of the Retention Pond bottom is estimated at 7296 feet msl. Thus, the waste rock depth within the Retention Pond foot print in the northwest area of the Ore Pad is estimated at 24 feet.

## 1.0 Introduction and Background

This report provides the results of the Treatment Pond Radiologic Characterization (TPRC) that was conducted at the Mt. Taylor Mine (Site) in Cibola County, near San Mateo, New Mexico. This TPRC was performed to check the status and estimate radiologic contamination exceeding the Site Radiation Cleanup Criteria (RCC) of 6.8 pCi/g Radium (Ra)-226 within six treatment ponds at the Site: Treatment Ponds 1, 4, 5, 6, 7 and 8. Any synthetic liners and previously identified radiologically impacted soils were removed from the treatment ponds during material removal efforts conducted in 2019, prior to this characterization. Additionally, various treatment pond concrete structures (hydraulic control structures) were left in place either intact or partially demolished, with concrete rumble remaining nearby most structures. The majority of the demolished concrete pieces were placed in piles south of the TPRC area. The TPRC area includes treatment pond dikes, bottoms, and concrete structures, as shown in the Figure 1. The methods and procedures used were consistent with the June 2020 Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands (2020 Work Plan) and the applicable survey methods described in the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM, EPA 2000a). The RCC specified in the March 2016 *Joint Guidance for the Cleanup and Reclamation of Existing Uranium Mining Operations in New Mexico* (EMNRD, 2016) (2016 Guidance) by the Energy, Minerals & Natural Resources Department (EMNRD) and the New Mexico Environment Department (NMED) was used for the investigation level (IL). The Ra-226 cleanup criteria of 5.0 pCi/g above the background level in land averaged over 100 square meters in surface soil (top six inches) specified in the Joint Guidance is taken from the UMTRCA (40 CFR 192) regulation, which is based on an unrestricted land use exposure scenario. A 6.8 pCi/g Ra-226 IL (5.0 pCi/g plus 1.8 pCi/g background level) has been established for the Site.

The Site was an underground uranium mine located in Cibola County, near San Mateo, New Mexico. The mine was developed by Gulf Mineral Resources Company (Gulf) in the 1970s and ore production occurred from 1979 to 1982. Following transfer of the Site to Chevron Resources Company in 1985, the ore production resumed and continued until 1990. Rio Grande Resources (RGR) acquired the Site in 1991. In 1999 the Site entered standby status under Mine Permit C1002RE with EMNRD. On December 29, 2017, the permit changed to an active status, and on December 3, 2019, RGR notified MMD of intentions to begin the Site closeout/closure process. The following sections describe the strategy, methods and procedures that were used and the results of the TPRC conducted at the Site.

## 2.0 Previous Radiologic Characterizations

Surface gamma radiation surveys were performed periodically within operationally controlled areas of the Site to monitor changes in radiological conditions during a period of remedial excavations in the Mine Water Treatment Unit (MWTU) ponds, construction of the disposal cell and placement of contaminated mine materials, and gradual removal of ore from the ore stockpile. The most recent gamma survey prior to this characterization, conducted March 2020, showed elevated gamma radiation levels in certain operational areas within the Controlled Area boundaries, including areas within the treatment ponds. The gamma

survey results are summarized in the June 2020 Work Plan, and indicate surface soils in portions of treatment Ponds 4 through 8, and the entire Pond 1 area exceed the 6.8 pCi/g Ra-226 IL.

## 3.0 Objective of the Radiological Characterization

The Site is a former uranium mine, therefore the surface and subsurface soil is expected to be impacted by radionuclides associated with the uranium decay series, with Ra-226 being the primary Constituent of Concern (COC). The objective of this characterization is to evaluate Ra-226 contamination exceeding the Site IL of 6.8 pCi/g Ra-226 in surface and subsurface soils to facilitate volume estimates of radiologic impacted material within the TPRC area.

## 4.0 Field Investigation

Field investigations for this characterization were conducted consistent with the June 2020 Work Plan and were performed during the period of November 2, 2023 through April 29, 2024. The specified TPRC areas are shown in Figure 1. The field investigations included both static 0.5-inch thick lead collimated and uncollimated (bare) 2x2 sodium iodide (NaI) detector gamma radiologic survey measurements and Differential Global Positioning System (DGPS) based bare detector gamma scan surveys, along with ex-situ soil screening, soil sampling, and offsite vendor laboratory confirmatory sample analysis. Geo-located gamma scans were conducted to provide Ra-226 concentration level estimates in surface soil and to assist in determining data point (static gamma, soil sampling) locations to assess surface and subsurface radiologic contamination relative to the IL. Ex-situ gamma radiation soil screening was performed on soil samples collected during this TPRC to provide real-time information to estimate surface and subsurface contamination depths. Offsite vender laboratory soil sample analysis was performed to confirm contamination relative to the IL levels estimated by the field ex-situ gamma radiation soil screening.

### 4.1 Surface Gamma Radiation Scan and Static Survey

The instrument configuration for direct gamma radiation level measurements during this characterization consisted of lead collimated and bare 2x2 NaI scintillation detectors (Eberline SPA-3) for detection of gamma radiation, coupled to a scaler/rate meter (Ludlum 2221 or Ludlum 2241). This instrument configuration is used widely for this type of survey and is recommended by the MARSSIM. The scaler/rate meters were interfaced with a sub-meter accurate DGPS with surveying software and a data logger/controller for electronically recording the gamma radiation levels to the corresponding geo-location coordinates. The coordinate system used for this work was the State Plane Coordinate System (NAD83, New Mexico West, US Feet) system. Direct gamma radiation surveys using a NaI scintillation detector provide radiation levels in counts per unit time, generally obtained as counts per minute (cpm).

During this characterization, systematic gamma radiation scan surveys using bare 2x2 NaI detectors were performed at the Site to determine the level of Ra-226 in surface soil within the characterization areas.

Although bare detectors do not avoid lateral gamma radiation shine, bare detectors have a large field of view and provide a large scan coverage area for an efficient and conservative lateral extent of contamination assessment. To better characterize the surface soil and to assist in the selection of data point locations, the surface gamma scan survey was performed at a higher density, 30-feet transect spacing compared to the March 2020 scan density of about 60-ft transect spacing. Thirty feet spaced geo-projected transects for Treatment Ponds 4, 5, 6, 7 and 8 were digitally created using a mapping software and loaded on the field data logger/controller. A gamma scan survey was not conducted at Treatment Pond 1 since the March 2020 gamma scan showed uniformly elevated measurements over the entire area making the additional surface gamma scan with a bare detector unnecessary in selecting data point locations. Data point locations were selected in Treatment Pond 1 by selecting locations that would adequately characterize the elements of the treatment pond as well as the areal extent of the area, as shown in Figure 2. Additionally, three of the data point locations in Treatment Pond 1 were biasedly located in material removal excavations performed prior to this characterization. Based on a conservative field of view (FOV) of at least six feet diameter for a bare 2x2 NaI detector for Ra-226 gamma radiations, scanning transects spacing of 30 feet would provide at least a 20% scan coverage. The gamma scan survey was performed by scanning along these transects with a bare 2x2 NaI detector at 12 inches above the ground surface at a scan rate of about three feet per second, with a data collection time interval of two seconds.

The geo-located gamma scan data includes the gamma scan point ID, date and time, location coordinates, and bare detector gamma cpm. The scan data was exported from the data logger and the bare detector cpm were converted to equivalent Ra-226 estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0005 x CPM)-7.3228 $R^2$ = 0.97) (2020 Work Plan). The scan data was mapped using mapping software, arranged in color coded ranges and then reviewed to identify areas that exceeded the IL. The color-coded range was structured to include the 6.8 pCi/g Ra-226 IL as shown in Figure 2. The characterization gamma scan survey included approximately 3,810 gamma scan data points within the TP characterization area. The gamma scan data was exported from the scan system data logger into an Excel file. The detector cpm was converted into equivalent estimated surface soil Ra-226 concentration in pCi/g using the Site-specific correlation for bare detectors as discussed in Section 4.5 of the 2020 Work Plan. A typical gamma scan data export table from the scan system data logger is shown in Table 1. Gamma scan survey data for this characterization are provided in an electronic file.

Thirty seven data point locations were selected within the Treatment Ponds 4, 5, 6, 7 and 8 characterization area based on surface gamma scan survey results and twelve data point locations were selected in the Treatment Pond 1 characterization area as described above, totaling in forty nine data point locations. One-minute static gamma radiation surveys were performed prior to collecting a soil sample at each data point location using a collimated 2x2 NaI detector. The survey data were recorded on Static Gamma Radiation Survey Forms, which are included in Appendix A. A Site-specific correlation for a 2x2 NaI 0.5-inch thick lead collimated detector was previously performed during the August 2023 Soil Radiologic Characterization. This correlation regression yielded an equation of Ra-226 = (cpm x 0.0016) – 8.41 with an acceptable $R^2$ value of 0.83. The collimated detector measurements were converted to soil Ra-226

concentrations using this correlation equation. The static gamma survey results are summarized in Table 2.

Treatment pond concrete structures located within the TPRC areas were surveyed by collecting a one minute collimated detector static gamma count on the intact structure walls. The static gamma survey was conducted with the collimated detector housing at contact with the concrete surface, which located the detector at 1.75 inches from the concrete surface. The results of the concrete surveys are included in Appendix B. In order to convert the collimated detector static survey results in cpm to the Ra-226 IL in pCi/g, the 2x2 NaI collimated detector was calibrated for the same survey geometry at the Department of Energy (DOE) Grants concrete calibration Pad. The calibration is included in Appendix C. The calibration indicates a level of 7,200 cpm for the 0.5 inch thick lead collimated detector at contact would be equivalent to the 6.8 pCi/g Ra-226 IL in concrete.

### 4.2 Soil Sampling and Ex-Situ Gamma Radiation Soil Screening

Soil sampling and on-Site ex-situ gamma radiation soil screening were performed from November 2, 2023, through April 29, 2024. These methods were used to estimate surface and subsurface soil Ra-226 contamination exceeding the IL at data point locations within the TPRC areas. The ex-situ gamma radiation soil screening was conducted to provide a real-time estimate of Ra-226 concentrations in soil samples. This method is more reliable than in-situ direct gamma radiation level measurements and allows for more certain real-time Ra-226 concentration assessments. The on-Site ex-situ soil screening method consists of selectively measuring the 609 KeV region gamma radiations of Bi-214, a decay product of Ra-226. A single channel analyzer (Ludlum L2221) integrated with a Ludlum 44-20 3x3 NaI scintillation detector was used to measure the 609 keV energy peak region of Bi-214. The soil sample was placed around the plastic lined detector in a heavily lead shielded counting chamber. The heavily shielded counting chamber lowers the system background counts, thus improving the system's minimum detectable concentration (MDC). A reference soil with the Ra-226 concentration of 6.6 pCi/g, comparable to the 6.8 pCi/g IL, was prepared and was used for soil screening during this characterization. The 6.6 pCi/g reference soil provides a conservative estimate of Ra-226 concentration in samples below the IL.

A total of 49 data point locations were selected for this TPRC, shown in Figure 2. Thirty seven data point locations were selected within the Treatment Pond 4, 5, 6, 7 and 8 characterization areas. The surface gamma scan indicated that no significant gamma shine was observed within these characterization areas. As a result, surface (0 to 6 inches) soil samples were not collected at the data points within this characterization area. The surface soil Ra-226 level was determined using the 0.5 inch thick collimated detector static gamma survey at these 37 data point locations. A one minute collimated detector static gamma survey provides a significantly higher certainty for a data point survey and the collimator mitigates any low level lateral gamma radiation shine from any nearby hot spots. A one minute collimated static gamma survey and both surface and subsurface soil samples were collected at the remaining twelve data point locations, which are all located within the Treatment Pond 1 characterization area.

Soil samples were collected from each of the 49 data point locations. The number and depth of the samples at each data point location varied depending upon location and soil screening results. At the 37 data points from the Treatment Pond 4, 5, 6, 7 and 8 characterization areas, a subsurface (6-12 inch) soil sample was collected, and ex-situ soil gamma screened. At five data point locations in this characterization area, TP-5B, TP-11, TP-15B, TP-16B and TP-21, a subsurface soil sample at a depth of 1-2 feet was collected and ex-situ soil screened since the 6-12 inch subsurface sample soil screening result was above the IL. At location TP-5B, an additional subsurface soil sample at a depth of 2-3 feet was collected since the 1-2 feet subsurface sample screening result was 6.0 pCi/g, near the IL. No additional subsurface soil samples were necessary at these locations. At each of the remaining 12 data points located in the Treatment Pond 1 characterization area, a surface and a subsurface (6 – 12") soil sample was collected, and ex-situ soil screened. At three data points located on the pond dike crests, TP-39, TP-41 and TP-46, the surface soil sample ex-situ soil screening results were above the IL. The 6-12 inch subsurface soil sample ex-situ soil screening results were above the IL in only one data point location, TP-36. The 1-2 feet subsurface soil sample ex-situ soil screening results at TP-36 was below the IL. No additional subsurface soils samples were necessary at these locations.

A backhoe was used to excavate a trench at each selected data point location for subsurface soil sample collection. The trenches were excavated in approximately 6 to 12 inches depth intervals. At each interval, a subsurface soil sample was collected from the base of the excavation for ex-situ soil screening. Stainless steel sampling trowels were used to collect all of the soil samples. The excavation continued until on-Site ex-situ soil screening indicated Ra-226 concentrations below the 6.8 pCi/g IL. The soil sample logs and the field soil screening forms are included in Appendix A. The soil ex-situ gamma screening data is summarized in Table 3, which includes Ra-226 concentrations of the samples relative to the 6.8 pCi/g IL.

Although the primary objective of the ex-situ gamma radiation soil screening was to determine the Ra-226 concentrations above or below the 6.8 pCi/g IL, Ra-226 concentrations were estimated in all soil samples collected and screened. A calibration/correlation of the ex-situ soil screening system was performed using a 6.6 pCi/g, a 25 pCi/g and a 50 pCi/g reference soil. This correlation is included in Appendix C. The estimated Ra-226 concentration of the subsurface soil samples determined using this correlation are included in Tables 3 and 4.

A total of nine, including one field quality assurance/quality check (QA/QC) duplicate, soil samples that were ex-situ soil screened on-Site were sent to an offsite vendor laboratory, Energy Laboratories, in Casper, WY. These soil samples were analyzed for Ra-226 using EPA Method 901.1 (modified for soil matrix) for the confirmation of the on-Site ex-situ soil screening results. The laboratory results report is included in Appendix D and are summarized in Table 3. As shown in the table, the estimated Ra-226 levels determined by the on-Site ex-situ soil screening are comparable with the laboratory Ra-226 results, specifically in regard to determining the Ra-226 levels above or below the IL.

### 4.3 Treatment Pond 1 Area Characterization Summary

In addition to subsurface soil samples, surface soil samples were collected at data points from within the Treatment Pond 1 characterization area to confirm the static gamma survey with a collimated detector, which indicated that the surface soil may not be elevated, as indicated by the 2020 bare detector surface soil gamma scan. As outlined in Tables 3 and 4, the soil screening results show that the surface and subsurface (6-12") soil Ra-226 levels are below the 6.8 pCi/g IL in all six samples located on the pond bottom in Treatment Pond 1. The surface and subsurface (6-12 inch) soil sample at location TP-35, which was collected from the base of a previously excavated area from the north dike, and the surface and subsurface (6-12 inch) soil sample at location TP-45, which was collected from the east dike crest, show Ra-226 levels below the 6.8 pCi/g IL. The ex-situ soil screening results show that samples collected from the crests of the dikes at four data point locations (TP-36, TP-39, TP-41 and TP- 46) the Ra-226 levels exceed the IL. Similar to TP-35, data point TP-41 was located at the base of a previous excavation. The subsurface soil (6-12 inch) Ra-226 levels are below the IL at all data point locations except for one location, TP-36. The screening results show the Ra-226 level at TP-36 in the 6-12 inch subsurface soil sample at 10.4 pCi/g, which is above the IL, and the 1-2 feet subsurface soil sample showed the Ra-226 level below the IL at 2.3 pCi/g. As shown in Figure 3, surface soil in the Treatment Pond 1 dikes exceeded the IL in some areas, but the subsurface soil is generally below the IL.

A one minute collimated detector static gamma survey was conducted on the concrete structure within the Treatment Pond 1 characterization area. The concrete structure was designated CS-10 and is located on the western dike inside slope. The gamma survey shows radiation cpm levels ranging from 9,408 to 25,471 cpm, above the 6.8 pCi/g Ra-226 IL equivalent of 7,200 cpm at all 7 survey points selected withing the concrete structure. Portions of the elevated gamma cpm levels may be due to apparent waste rock material near and surrounding the concrete structure, and from concrete surface staining from the historic retention of mine wastewater and sediments. A gamma radiation level of 90,000 cpm was observed in the bottom of the concrete sump, likely due to the remaining layer of mine waste sediments and soil. Further direct radiation surveys of the concrete structure in place may not be effective. Removal of the concrete structures and radiation surveys of the underlying soil and sampling and surveying of the concrete may provide a better understanding of the Ra-226 levels within the concrete structure.

### 4.4 Treatment Pond 4, 5, 6 and 7 Area Characterization Summary

Because lateral gamma radiation shine was not a significant concern at these ponds, the surface soil (0-6 inch) Ra-226 levels were determined by a collimated detector one minute gamma static survey. As shown in Table 2, Table 4, and Figure 2, the surface static gamma survey results show the surface soil (0-6 inch) Ra-226 level in Treatment Pond 4, 5, 6 and 7 pond bottoms are below the IL, except for areas that are down gradient of the concrete structures and at a few isolated areas of elevated gamma radiation levels, likely remnants from previous removal efforts. The elevated surface static gamma levels near the concrete structures appear to be due to contaminated sediment in the concrete structure sumps and from apparent

mine waste material around the structures. The soil along the north dike crest of Treatment Pond 4 appears to be generally below the IL. The surface soil along the east and west dike crests are generally above the IL. The subsurface soil along the east and west dike crests are generally below the IL, except for the 6-12 inch subsurface sample at TP-11. Ex-situ soil screening results from the 6-12 inch subsurface sample at TP-11 of 64.4 pCi/g is likely due to apparent mine waste rock visible in the area. The Ra-226 levels in the subsequent 1–2 feet subsurface soil sample at TP-11 is below the IL. The surface soil on the south dike crest of Treatment Pond 4 appears to be below the IL, except near the concrete structure. The soil on the west dike outside slopes and crests of Treatment Pond 5, 6 and 7 are generally below the IL, except near the concrete structures. The surface soil on the east dike crest of Treatment Pond 5 is above the IL at various isolated locations, shown in Figures 2 and 3.

One minute collimated detector static gamma surveys conducted at nine concrete structures, shown in Figure 1, located on the dike inside slopes and/or crests at Treatment Pond 4, 5, 6, and 7 show gamma radiation levels ranging from 5,500 cpm to 45,600 cpm. As stated previously, the IL equivalent cpm for the concrete survey is 7,200 cpm. Portions of the elevated gamma cpm levels may be due to apparent waste rock material near and surrounding the concrete structure, and from concrete surface staining from the historic retention of mine wastewater and sediments. Mine waste sediments were also observed inside all the concrete structure sumps, which showed elevated gamma survey readings of up to 31,000 cpm. The concrete structure static gamma survey forms are included in Appendix B. In general, the majority of the concrete comprising the structures are likely to be below the IL, but it will be difficult to assess by gamma radiation surveys as concrete surface staining from the retention of mine waste water and sediments and apparent waste rock material near and surrounding the concrete structure are still present. Further direct radiation surveys of the concrete structure in place may not be effective.

Removal of the concrete structures and radiation surveys of the underlying soil and sampling and surveying of the concrete may provide a better understanding of the Ra-226 levels within the concrete structure. Several random pieces of the demolished concrete structures were surveyed for gamma radiation. The demolished concrete structure pieces are piled in fairly low gamma shine area south of Treatment Pond 7. The results, included in Appendix B, show all pieces surveyed were below the 7200 cpm IL, which supports the assumption that the sediments and apparent waste rock material near and surrounding the concrete structures may be impacting the direct gamma survey of the in-place concrete structures.

### 4.5 Treatment Pond 8 Area Characterization Summary

As shown in Table 2, Table 4, Figure 2 and 3, the surface static gamma survey results show the surface soil (0-6 inch) Ra-226 level in the bottom of Treatment Pond 8 is below the IL, except in a small isolated area at data point TP-6, which is estimated by ex-situ soil screening at 9 pCi/g. The 6–12 inch subsurface soil sample at TP-6 showed Ra-226 level at 3.1 pCi/g, well below the IL. Surface soil Ra-226 levels in portions of the south and west dike slopes and crests are above the IL. Ra-226 in the subsurface soil at these locations are below the IL. Elevated surface gamma scans with a bare detector along the east dike crest and outside

slope appear to be mostly due to lateral gamma radiation shine from adjacent areas outside of the Treatment Pond 8 characterization area.

### 4.6 Borrow Area A Soil Piles

Two soil piles located in the East Borrow area were sampled to estimate Ra-226 levels relative to the IL. Soil in these piles apparently came from the mine water treatment ponds. Pile 1 contained shrub/wood debris and treatment pond waste residue. Pile 2 contained fine treatment pond waste residue along with pieces of synthetic liner. Gamma exposure rates were measured at several locations on each pile. Exposure rates on pile 1 ranged from 100 to 200 uR/hr, and ranged from 100 to 300 uR/hr on Pile 2. A five-point composite soil sample was collected from both the surface and from within Pile 1. A soil sample was not collected from Pile 2 because the gamma exposure rate measurements indicated Ra-226 levels significantly above the IL and the fine pond waste residue on the surface of the pile posed airborne radiation safety concerns and the spread of contamination in the area due to windy conditions. As shown in Table 3, ex-situ soil gamma screening of the samples from Pile 1 indicates Ra-226 levels significantly above the IL.

## 5.0 Soil Sampling and Analysis

Soil samples from the Treatment Pond areas collected for on-Site ex-situ gamma radiation soil screening were collected consistent with the 2020 Work Plan. Field QA/QC duplicate samples were split at a frequency of 10% of the total number of soil samples collected. A total of 67 surface and subsurface soil samples were collected during this characterization. Field sampling equipment used for soil sampling included: stainless steel scoops, bowls, and spoons that were decontaminated between sample locations. The soil sampling equipment decontamination was conducted by brushing off loose visible soil and wiped with clean towels. Excavator buckets were cleaned by removing any loose, visible soil. Any soils excavated from the test pits were returned to the test pit excavations from which the soil came. Personal protection equipment (PPE), such as gloves, were brushed off and scanned for residual contamination and were disposed of.

Surface and subsurface soil samples were analyzed by on-Site ex-situ gamma radiation soil screening (AVM SOP-4) to estimate Ra-226 concentrations. A completed Chain-of-Custody (COC) along with confirmatory soil samples were placed in labeled Ziploc bags, and packaged in a cooler with a sealed lid and shipped to Energy Laboratories, Inc for Ra-226 analysis. The soil samples were analyzed for Ra-226 with a reporting limit of 0.5 pCi/g, using EPA Method 901.1 (modified for soil matrix). The completed COCs are included with the analytical results reports in Appendix D.

## 6. 0 Quality Assurance and Quality Control Measures

QA/QC measures were implemented during this characterization to ensure that decisions were made based on data of acceptable quality. All radiologic survey instruments have been calibrated at least annually. Additionally, operational functions checks were performed on all radiologic instruments daily prior to use.

The calibration and function check documents are included in Appendix C. During this characterization, no instruments were found to be out of calibration or inoperable as indicated by the operational function checks. The instrument background measurements for bare 2x2 NaI detectors during daily operational function checks were less than 10,000 cpm as shown in Appendix C. The bare detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of six feet diameter. The 2x2 NaI detector response factor is determined to be 0.0005 pCi/g/cpm from the linear regression for the Site-specific correlation included in Appendix C. Based on the above detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a scan survey at a scan speed of three feet per second, calculated using MARSSIM guidance, were less than 1.0 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The instrument background measurements for the 0.5 inch thick lead collimated 2x2 NaI detectors during daily operational function checks were less than 3,200 cpm, as shown in Appendix C. The bare detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of 1.5 feet diameter. The collimated 2x2 NaI detector response factor is determined to be 625 cpm/pCi/g from the linear regression for the Site-specific correlation included in Appendix C. Based on the above collimated detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a one minute static survey, calculated using MARSSIM guidance, was less than 0.5 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The ex-situ soil gamma radiation screening system was calibrated prior to mobilization in the field and daily operational function checks were performed prior to use. The calibration and function check documentation are included in Appendix C. Based on the highest system background (blank) measurements from daily operational function checks and efficiency (pCi/g/cpm), the highest Ra-226 MDC for the screening system calculated was less than 1.0 pCi/g, significantly less than the 6.8 pCi/g IL. The MDCs during the supplemental characterization met the QA objective.

The QA/QC measures also included nine field QA/QC duplicate soil samples out of the 67 soil samples collected sent to the off-site vendor laboratory for analysis to confirm contamination relative to the IL levels estimated by the field ex-situ gamma radiation soil screening. The QA/QC duplicate vendor laboratory results are included in Table 3. All QA/QC sample results confirm Ra-226 concentration levels relative to the IL level determined by the field ex-situ gamma radiation soil screening. The Ra-226 concentration in QA/QC duplicate samples estimated by on-sit ex-situ gamma radiation soil screening are comparable to the off-site vendor laboratory analytical results.

# ANALYTICAL SUMMARY REPORT

May 24, 2024

Rio Grande Resources Corporation
PO Box 1150
Grants, NM 87020-1150

Work Order: C24040791 Quote ID: C16056

Project Name: MTM TP Soil Characterization

Energy Laboratories, Inc. Casper WY received the following 10 samples for Rio Grande Resources Corporation on 4/24/2024 for analysis.

| Lab ID | Client Sample ID | Collect Date | Receive Date | Matrix | Test |
|---|---|---|---|---|---|
| C24040791-001 | TP-11 [6-12]inches | 11/13/23 13:45 | 04/24/24 | Solid | Gamma Sample Preparation Drying/Grinding, Radiochemistry Gross Gamma |
| C24040791-002 | TP-15B [6-12]Inches | 11/14/23 8:25 | 04/24/24 | Solid | Same As Above |
| C24040791-003 | TP-11 [1-2]Feet | 11/16/23 11:05 | 04/24/24 | Solid | Same As Above |
| C24040791-004 | TP-15B [1-1.5]Feet | 11/16/23 11:35 | 04/24/24 | Solid | Same As Above |
| C24040791-005 | TP-41 [0-6]Inches | 04/16/24 8:45 | 04/24/24 | Solid | Same As Above |
| C24040791-006 | TP-46 [6-12]Inches | 04/16/24 10:25 | 04/24/24 | Solid | Same As Above |
| C24040791-007 | TP-36 [6-12]Inches | 04/16/24 11:00 | 04/24/24 | Solid | Same As Above |
| C24040791-008 | TP-41 [6-12]Inches | 04/16/24 11:15 | 04/24/24 | Solid | Same As Above |

The analyses presented in this report were performed by Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the report package. Any issues encountered during sample receipt are documented in the Work Order Receipt Checklist.

The results as reported relate only to the item(s) submitted for testing. This report shall be used or copied only in its entirety. Energy Laboratories, Inc. is not responsible for the consequences arising from the use of a partial report.

If you have any questions regarding these test results, please contact your Project Manager .

Report Approved By:

**CLIENT:** Rio Grande Resources Corporation
**Project:** MTM TP Soil Characterization
**Work Order:** C24040791

**Report Date:** 05/24/24

# CASE NARRATIVE

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

BRANCH LABORATORY LOCATIONS
eli-b - Energy Laboratories, Inc. - Billings, MT
eli-g - Energy Laboratories, Inc. - Gillette, WY
eli-h - Energy Laboratories, Inc. - Helena, MT

ISO 17025 DISCLAIMER:
The results of this Analytical Report relate only to the items submitted for analysis.

ENERGY LABORATORIES, INC. - CASPER,WY certifies that certain method selections contained in this report meet requirements as set forth by the above accrediting authorities. Some results requested by the client may not be covered under these certifications. All analysis data to be submitted for regulatory enforcement should be certified in the sample state of origin. Please verify ELI's certification coverage by visiting www.energylab.com

ELI appreciates the opportunity to provide you with this analytical service. For additional information and services visit our web page www.energylab.com.

# LABORATORY ANALYTICAL REPORT

Prepared by Casper, WY Branch

**Client:** Rio Grande Resources Corporation
**Project:** MTM TP Soil Characterization
**Lab ID:** C24040791-001
**Client Sample ID:** TP-11 [6-12]

**Report Date:** 05/24/24
**Collection Date:** 11/13/23 13:45
**DateReceived:** 04/24/24
**Matrix:** Solid

| Analyses | Result | Units | Qualifiers | RL | MCL/ QCL | Method | Analysis Date / By |
|---|---|---|---|---|---|---|---|
| **RADIONUCLIDES, GAMMA** | | | | | | | |
| Radium 224 | -0.8 | pCi/g-dry | U | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 224 precision (±) | 8.0 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 224 MDC | 13.3 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 226 | 61.5 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 226 precision (±) | 1.4 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 226 MDC | 0.7 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 228 | 0.4 | pCi/g-dry | U | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 228 precision (±) | 1.2 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |
| Radium 228 MDC | 1.7 | pCi/g-dry | | | | E901.1 | 05/16/24 15:53 / haw |

**Report Definitions:**
RL - Analyte Reporting Limit
QCL - Quality Control Limit
U - Not detected at Minimum Detectable Concentration (MDC)
MCL - Maximum Contaminant Level
ND - Not detected at the Reporting Limit (RL)

# LABORATORY ANALYTICAL REPORT

Prepared by Casper, WY Branch

| Radium 228 MDC | | 0.44 | pCi/g-dry | | | | | | | |

- Duplicate RPD for Ra224 is outside of the acceptance range for this analysis. However, the RER is less than or equal to the limit of 3, the RER result is 0.82. The RER result for Ra226 is 0.19 and Ra228 is 0.17.

**Qualifiers:**

RL - Analyte Reporting Limit

ND - Not detected at the Reporting Limit (RL)

R - Relative Percent Difference (RPD) exceeds advisory limit

U - Not detected at Minimum Detectable Concentration (MDC)

### Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

The reference date for Radon analysis is the sample collection date. The reference date for all other Radiochemical analyses is the analysis date. Radiochemical precision results represent a 2-sigma Total Measurement Uncertainty.

For methods that require zero headspace or require preservation check at the time of analysis due to potential interference, the pH is verified at analysis. Nonconforming sample pH is documented as part of the analysis and included in the sample analysis comments.

## 1.0 Introduction and Background

This report provides the results of the North Controlled Area (NCA) Soil Radiologic Characterization (SRC) that was conducted at the Mt. Taylor Mine (Site) in Cibola County, near San Mateo, New Mexico. This NCA SRC was performed to check the status and estimate radiologic contamination in soil exceeding the Site Radiation Cleanup Criteria (RCC) of 6.8 pCi/g Radium (Ra)-226, which is also used as the Site Investigation Level (IL). The NCA SRC area includes the Mine Water Treatment Area, the Ore Pad Runoff Retention Pond, the North Diversion Channel, Borrow Area A, the Marquez Arroyo bed, and the area between the Marquez Arroyo and the northern boundary fence of the NCA. The previously characterized Mine Water Treatment Ponds (1, 4, 5, 6, 7 & 8), the Ore Pad Area and the two active Mine Water Treatment Ponds (2 & 3) are not included in this NCA SRC. The methods and procedures used were consistent with the agency May 2022 approved June 2020 Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands (Work Plan), and the applicable survey methods described in the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM, EPA 2000a). The RCC specified in the March 2016 *Joint Guidance for the Cleanup and Reclamation of Existing Uranium Mining Operations in New Mexico* (EMNRD, 2016) (2016 Guidance) by the Energy, Minerals & Natural Resources Department (EMNRD) and the New Mexico Environment Department (NMED) was used for the investigation level (IL) the NCA SRC. The Ra-226 cleanup criteria of 5.0 pCi/g above the background level in land averaged over 100 square meters in surface soil (top six inches) specified in the Joint Guidance is taken from the UMTRCA (40 CFR 192) regulation, which is based on an unrestricted land use exposure scenario. A 6.8 pCi/g Ra-226 IL (5.0 pCi/g plus 1.8 pCi/g background level) has been established for the Site.

The Site was an underground uranium mine located in Cibola County, near San Mateo, New Mexico. The mine was developed by Gulf Mineral Resources Company (Gulf) in the 1970s and ore production occurred from 1979 to 1982. Following the transfer of the Site to Chevron Resources Company in 1985, the ore production resumed and continued until 1990. Rio Grande Resources (RGR) acquired the Site in 1991. In 1999 the Site entered standby status under Mine Permit C1002RE with EMNRD. On December 29, 2017, the permit changed to an active status, and on December 3, 2019, RGR notified EMNRD of intentions to begin the Site closeout/closure process. The following sections describe the strategy, methods and procedures that were used and the results of the NCA SRC conducted at the Site.

## 2.0 Previous Radiologic Characterizations

Surface gamma radiation surveys were performed periodically within operationally controlled areas of the Site, including the NCA, to monitor changes in radiological conditions during a period of remedial excavations in the Mine Water Treatment Ponds, construction of the disposal cell, placement of contaminated mine materials, and the gradual removal of ore from the Ore Pad stockpile. The most recent gamma survey in this area prior to this characterization was conducted in March 2020 and showed gamma radiation levels exceeding the 6.8 pCi/g Ra-226 IL in numerous areas at the Site, including areas within the NCA. The 2020 gamma survey results are summarized in the Work Plan.

## 3.0 Objective of the Soil Radiological Characterization

The Site is a former uranium mine, therefore the surface and subsurface soil is expected to be impacted by radionuclides associated with the uranium decay series, with Ra-226 being the primary Constituent of Concern (COC). The objective of this characterization is to evaluate Ra-226 contamination exceeding the 6.8 pCi/g Ra-226 IL in surface and subsurface soils to facilitate the estimation of the volume of radiologic impacted soil within the NCA SRC area.

## 4.0 Field Investigation

Field investigations for this NCA SRC were conducted consistent with the Work Plan and were performed during the period of July 2024 through January 2025. The field investigation included both 0.5-inch thick lead collimated and bare (uncollimated) 2x2 sodium iodide (NaI) detector Differential Global Positioning System (DGPS) based gamma radiation scan surveys, and measurements. Additionally, static gamma radiation surveys, soil sampling, ex-situ soil screening, and offsite vendor laboratory confirmatory sample analysis were utilized during this SRC. The DGPS based gamma scan surveys were conducted to provide lateral Ra-226 concentration level estimates in surface soils. To assess subsurface radiological contamination, areas of potentially similar vertical extent of contamination were selected based on the DGPS gamma scan surveys, and data point (static gamma survey and subsurface soil samples) locations were selected to provide an area contamination depth profile estimation. Ex-situ gamma radiation soil screening was performed on the soil samples collected to provide real-time information to estimate surface and subsurface Ra-226 contamination levels. Offsite vender laboratory soil sample analysis was utilized to confirm the contamination levels estimated by ex-situ soil screening.

### 4.1 Surface Gamma Radiation Scan and Static Surveys

The instrument configuration used for direct gamma radiation level measurements during this characterization consisted of 0.5 inch thick lead collimated and bare 2x2 NaI scintillation detectors (Eberline SPA-3 or Ludlum 44-10) coupled to a scaler/rate meter, such as a Ludlum 2221 or Ludlum 2241. This instrument configuration is widely used for this type of survey and is recommended by the MARSSIM. The scaler/rate meters were interfaced with a sub-meter accurate DGPS with surveying software and a data logger/controller for electronically recording the gamma radiation levels to the corresponding geo-location coordinates. The coordinate system used for this work was the State Plane Coordinate System (NAD83, New Mexico West, US Feet) system. The direct gamma radiation surveys using a NaI scintillation detector provide radiation levels in counts per minute (cpm).

During this characterization, systematic gamma radiation scan surveys using bare 2x2 NaI detectors were performed at the Site to estimate the level of Ra-226 in surface soil within the characterization areas. Although bare detectors do not avoid lateral gamma radiation shine, bare detectors have a large field of view and provide a large scan coverage area for an efficient and conservative lateral extent of

contamination assessment. To better characterize the surface soil and to assist in the selection of data point locations, the surface gamma scan survey was performed at a higher density, 25-feet transect spacing, compared to the March 2020 scan density of about 60-ft transect spacing. Based on a conservative field of view (FOV) of about ten feet diameter for a bare 2x2 NaI detector for Ra-226 gamma radiation, scanning transects spacing of 25 feet would provide at least a 40% scan coverage, which is sufficient to identify and characterize any surface soil contamination. The gamma scan survey was performed by scanning along these transects with the detector at 12 inches above the ground surface at a scan rate of about three feet per second, with a data collection time interval of two seconds. A Bare detector gamma scan survey was performed in areas away from the Ore Pad, which could result in lateral gamma radiation shine. In areas near the Ore Pad, a 0.5 inch thick lead collimated detector was used to mitigate lateral gamma radiation shine. The bare/collimated detector gamma scan boundary is shown in Figure 2.

Twenty-five feet spaced geo-projected transects within the NCA were digitally created using a mapping software and loaded on the field data logger/controller. During this characterization, a gamma scan survey was not conducted in the Ore Pad Runoff Retention Pond since previous gamma scan surveys showed uniformly and significantly elevated measurements compared to the IL, making additional surface gamma scan surveys unnecessary in assisting with selecting data point locations for subsurface investigation.

The geo-located gamma scan data includes the gamma scan point ID number, date and time, location coordinates, and detector cpm. The scan data was exported from the data logger and the bare detector cpm were converted to equivalent Ra-226 estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0005 x CPM)-7.32 $R^2$ = 0.97). The collimated detector cpm data was converted to equivalent Ra-226 estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0016 x CPM)-7.5 $R^2$ = 0.83). The 20,357 discrete gamma scan points collected during the gamma scan survey were exported from the scan system and the detector cpm data was converted into the equivalent estimated surface soil Ra-226 pCi/g concentration using the appropriate Site-specific correlation. The data was then plotted using a mapping software, shown in Figure 2, and arranged in graduated color ranges, then reviewed to identify areas that exceeded the Ra-226 IL. A typical gamma scan data export table from the scan system data logger is shown in Table 1. Gamma scan survey data collected during this characterization are provided in an electronic file.

As previously discussed, areas of potentially similar vertical extent of contamination were selected based on the DGPS gamma scan surveys. A total of forty test pit (TP) data point locations, shown in Figure 3, were selected within these areas for the estimation of the vertical extent of Ra-226 contamination above IL. A one-minute collimated detector static gamma radiation survey was performed to estimate surface soil Ra-226 levels prior to collecting any soil samples at each data point location. Of the 40 TP data point locations, two were in the Ore Pad Retention Pond and one was located in the bed of the Marquez Arroyo. Additionally, seven investigation (INV) data point locations were selected where gamma scan surveys showed an isolated area with Ra-226 levels slightly above the IL. The investigation (INV) locations were inspected and one-minute collimated detector static gamma measurements were performed to determine if subsurface soil sampling was necessary. The survey data was recorded on Static Gamma Radiation Survey

Forms, which are included in Appendix A. The collimated detector measurements were converted to soil Ra-226 concentrations using the correlation equation for the collimated detector. The static gamma survey results are summarized in Table 2.

### 4.2 Soil Sampling and Ex-Situ Gamma Radiation Soil Screening

Soil sampling and on-site ex-situ gamma radiation soil screening were performed during October 2024 to January 2025 to estimate the subsurface soil Ra-226 contamination exceeding the IL. Surface (0 to 6 inches) soil samples were not collected at the data points during this characterization. The estimated surface soil Ra-226 level was determined from one-minute collimated detector static gamma radiation surveys. A one-minute collimated detector static gamma radiation survey provides a significantly higher certainty for a surface soil Ra-226 estimate than a two second integration gamma radiation scan survey provides. The use of a collimated detector mitigates any lateral gamma radiation shine from any nearby elevated concentration areas

Ex-situ gamma radiation soil screening was conducted to provide a real-time estimate of Ra-226 concentrations in soil samples to determine depth of subsurface soil sampling. This method is more reliable than in-situ direct gamma radiation level measurements and allows for a more reliable real-time Ra-226 concentration assessment. The on-site ex-situ soil screening method consists of selectively measuring the 609 KeV region gamma radiation of Bi-214, a decay product of Ra-226. A single channel analyzer (Ludlum L2221 or Ludlum 3003) integrated with a Ludlum 44-20 3x3 NaI scintillation detector was used to measure the 609 keV energy peak region of Bi-214. The soil sample was placed around the plastic lined detector in a heavily lead shielded counting chamber. The heavily shielded counting chamber lowers the system background counts thus, improving the system's minimum detectable concentration (MDC). A reference soil with the Ra-226 concentration of 6.6 pCi/g, comparable to the 6.8 pCi/g IL, was prepared and was used for soil screening during this characterization. The 6.6 pCi/g reference soil provides a conservative estimate of Ra-226 concentration in samples below the IL.

Subsurface soil samples were collected from each of the 47 data point (TP & INV) locations. The number and depth of the samples at each data point location varied depending upon location and soil screening results. A backhoe was used to excavate a trench for subsurface soil sample collection at each selected data point location, except for the subsurface soil samples collected from the Ore Retention Pond Bottom (TP-21 and TP-26), the North Diversion Channel Bed (TP-32 and TP-34), the Marquez Arroyo (TP-30), and the area between the Marquez Arroyo and the northern NCA boundary fence (TP-17, TP-25 and TP-33). At these locations, a hand auger was used to collect the subsurface soil samples since backhoe access was not practical. The trenches were excavated in approximately 6 to 12 inches depth intervals, depending on soil type and visual observations. At each interval, a subsurface soil sample was collected from the base of the excavation for ex-situ gamma radiation soil screening. Stainless steel sampling trowels, bowls and sieves were used to collect the soil samples. The excavation continued until on-site ex-situ gamma radiation soil screening indicated that Ra-226 concentrations were below the 6.8 pCi/g IL. The soil sample

logs and the field soil screening forms are included in Appendix A. The ex-situ gamma radiation screening data is summarized in Table 3, which includes estimated Ra-226 concentrations of the samples relative to the 6.8 pCi/g IL.

At 34 of the 47 data point locations, a 6-12 inch below ground surface (bgs) subsurface soil sample was collected, and ex-situ soil gamma screened. Furthermore, at five of those 37 data point locations, a subsurface soil sample at a depth of 1-2 feet bgs was collected and ex-situ soil screened since the 6–12-inch bgs subsurface sample soil screening result was above the IL. The subsurface soil samples from the two data point locations on the bottom of the Ore Retention Pond were collected at a depth of 3-4 feet below ground surface (bgs) since the shallow subsurface sample screening result was above the IL. At location TP-19, a subsurface soil sample was collected at a depth of 4.5 to 5.0 feet bgs since waste rock was observed from the ground surface to a depth of 4.5 feet bgs. An additional subsurface soil sample was collected at TP-19 at 5.0-5.5 feet bgs to confirm that the soil below 4.5 feet bgs is below the 6.8 pCi/g IL.

Although the primary objective of the ex-situ gamma radiation soil screening was to determine the Ra-226 concentrations above or below the 6.8 pCi/g IL, Ra-226 concentrations were estimated in all soil samples collected and screened. A calibration/correlation of the ex-situ soil screening system was performed using a 6.6 pCi/g, a 25 pCi/g and a 50 pCi/g reference soil. This correlation is included in Appendix B. The estimated Ra-226 concentrations of the subsurface soil samples are included in Tables 3 and 4.

A total of twelve, including one field quality assurance/quality check (QA/QC) duplicate, of the soil samples that were ex-situ gamma radiation soil screened on-site were sent to an offsite vendor laboratory for analysis, Energy Laboratories, in Casper, WY. These soil samples were analyzed for Ra-226 using EPA Method 901.1 (modified for soil matrix) for confirmation of the on-site ex-situ soil screening results. The laboratory results report is included in Appendix C and are summarized in Table 3. As shown in the table, the estimated Ra-226 levels determined by the on-site ex-situ soil screening are comparable with the vendor laboratory Ra-226 results, specifically in regards to determining that the Ra-226 levels are above or below the IL.

### 4.3 NCA Characterization Summary

As described previously, this NCA SRC included the areas shown in Figure 1. The entire NCA SRC area consists of approximately 46 acres. The soil in approximately a 23 acre area is below the 6.8 pCi/g Ra-226 IL. In the remaining 23 acre area, the soil exceeds the IL and ranges from the ground surface to a depth of 4.5 feet bgs. The depth of soil exceeding the IL at each data point (TP and INV) are summarized in Table 4 and shown in Figure 4. Figure 5 shows areas within the characterization area with soil exceeding the IL at various contamination depths. The areas and estimated volume of in-situ soil exceeding the IL within this characterization are summarized in Table 5. The excavated volume of soil exceeding the IL may be higher than the estimated in-situ volume due to the swell factor and the excavation equipment and technique used.

### 4.3.1 Mine Water Treatment Area Characterization Summary

The Mine Water Treatment Area consists of approximately 31 acres. Included in this area is the area between the Marquez Arroyo and the NCA fence. As shown in Figure 2, the gamma scan survey showed that the soil in the area generally west of the Treatment Ponds 4, 5, 6, and 7 is below the 6.8 pCi/g Ra-226 IL, except for a few isolated small areas. In these small isolated areas, the soil exceeding the IL ranges from 0.5 feet to 3.5 feet. The depth of soil exceeding the IL in the middle of the Mine Water Treatment Area, the area surrounding the Treatment and Active Ponds, generally ranged from 0.5 feet to 1.5 feet. The depth of soil exceeding the IL in the eastern section of the area, the areas near the Ore Pad and Ore Retention Pond, generally ranged from 0.5 feet to 4.5 feet.

### 4.3.2 Marquez Arroyo Bed Characterization Summary

A gamma scan survey of the Marquez Arroyo bed surface was conducted using a 0.5-inch lead collimated detector to mitigate any gamma radiation shine from the walls of the arroyo. As shown in Figure 2, there are only a few isolated locations that showed Ra-226 levels just above the IL. As shown in Table 2, the collimated detector gamma static survey at those isolated spots showed the bed surface soils well below the IL. A subsurface soil sample at a depth of 0.5 to 1.0 foot bgs was collected using a hand auger at the highest static gamma survey result location, TP-30. The gamma soil screening of the subsurface soil sample showed Ra-226 levels well below the IL. The Marquez Arroyo bed soil is below the Ra-226 IL.

### 4.3.3 Ore Retention Pond Characterization Summary

A gamma scan survey within the Ore Pad Retention Pond was not conducted because the 2020 gamma scan showed that the pond bottom surface soil has significantly elevated levels of Ra-226 above the IL. The two locations (TP-21 & TP-26) from the bottom of the pond were selected for subsurface characterization. The collimated detector static gamma survey at these two locations confirmed that the surface soil Ra-226 levels are significantly above the IL. Because of practical concerns for backhoe access into the Ore Retention Pond, subsurface soil samples were collected using a hand auger. As shown in Table 4 and Figure 4, the pond bottom subsurface soil sample gamma screening results show the Ra-226 level exceeding the IL range from two feet bgs at TP-21 to three feet at TP-26 bgs. The ground surface elevation at TP-26 is about one foot higher than at TP-21. The Ore Retention Pond crest and the outside slopes of the dikes are covered by an approximate one-foot layer of soil which is slightly above the IL. Waste rock was observed under the approximately one-foot soil layer. Waste rock is visible on the inside slope of the dikes from the crest to the base. It is likely that the entire dike profile and approximately one foot bgs under the dike base are likely to exceed the Ra-226 IL. Table 5 does not include the approximate volume of the Ore Retention Pond dikes impacted soil.

### 4.3.4 North Diversion Channel Characterization Summary

A lead collimated detector gamma scan survey of the banks and bed of the North Diversion Channel was conducted and showed the surface soil Ra-226 levels are above the IL. The western berm of the channel is adjacent the Ore Pad and exceeds the Ra-226 IL through its entire depth profile. The depth of Ra-226 levels above the IL in the eastern berm ranges from 0.5 to 1.0 foot bgs. As shown in Figures 4 and 5, the depth of Ra-226 levels exceeding the IL in the North Diversion Channel bed ranges from one to two feet bgs.

### 4.3.5 Borrow Area A Characterization Summary

As shown in Figure 2, the collimated detector gamma scan survey of Borrow Area A showed surface soil that exceeds the Ra-226 IL along the western, northern and southern perimeter areas. The subsurface soil samples and ex-situ gamma soil screening results show that the soil exceeding the Ra-226 IL is generally limited to 0.5-foot bgs, except for a small area near the southeast corner of the Borrow Area A, where the Ra-226 level exceeds the IL at a depth of about one-foot bgs. During the gamma scan of the Borrow Area A, scattered debris was observed on the surface and some debris such as cables and pipes were protruding out of the ground surface along the perimeter of the area. Additionally, at data point location TP-38, a subsurface soil sample was not collected due to the presence of metal debris restricting excavation past approximately 8 inches bgs. It is likely that the soil around buried debris may have soil Ra-226 levels above the IL. A magnetometer survey of the area may be necessary to locate any buried debris.

## 5.0 Soil Sampling and Analysis

Soil samples from the NCA collected for on-site ex-situ gamma radiation soil screening were collected consistent with the Work Plan. Field QA/QC duplicate samples were ex-situ gamma radiation soil screened at a frequency of 10% of the total number of soil samples screened. A total of 70 surface and subsurface soil samples were collected for the NCA characterization. Field sampling equipment used for soil sampling included: stainless steel scoops, hand auger, bowls, sieve, and spoons that were decontaminated between sample locations. The soil sampling equipment decontamination was conducted by brushing off loose visible soil and when necessary was rinsed with distilled water, then wiped with clean towels. The rinsed water was disposed of in Active Pond No. 2. Excavator buckets were cleaned by removing any loose, visible soil. Any soils excavated from the test pits were returned to the test pit excavations from which the soil came. Personal protection equipment (PPE), such as gloves, were brushed off and scanned for residual contamination and were disposed of.

Subsurface soil samples were analyzed by on-site ex-situ gamma radiation soil screening to estimate Ra-226 concentrations. Twelve QA/QC confirmatory soil samples were placed in labeled Ziploc bags and packaged along with a completed chain of custody in a cooler with a custody sealed lid and shipped to Energy Laboratories, Inc for Ra-226 analysis. The soil samples were analyzed for Ra-226 with a reporting limit of

0.5 pCi/g, using EPA Method 901.1 (modified for soil matrix). The completed chain of custody and the analytical results are included in Appendix C.

## 6. 0 Quality Assurance and Quality Control Measures

QA/QC measures were implemented during this characterization to ensure that decisions were made based on data of acceptable quality. All radiologic survey instruments have been calibrated at least annually. Additionally, operational functions checks were performed on all radiologic instruments daily prior to use. The calibration and function check documents are included in Appendix B. During this characterization, no instruments were found to be out of calibration or inoperable as indicated by the operational function checks. The instrument background measurements for bare 2x2 NaI detectors during daily operational function checks were less than 10,000 cpm as shown in Appendix B. The bare detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of six feet diameter. The 2x2 NaI detector response factor is determined to be 0.0005 pCi/g/cpm from the linear regression for the Site-specific correlation included in Appendix B. Based on the above detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a scan survey at a scan speed of three feet per second, calculated using MARSSIM guidance, were less than 1.0 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The instrument background measurements for the 0.5 inch thick lead collimated 2x2 NaI detectors during daily operational function checks were less than 3,200 cpm, as shown in Appendix B. The collimated detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of 1.5 feet diameter. The collimated 2x2 NaI detector response factor is determined to be 625 cpm/pCi/g from the linear regression for the Site-specific correlation included in Appendix B. Based on the above collimated detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a one minute static survey, calculated using MARSSIM guidance, was less than 0.5 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The ex-situ soil gamma radiation screening system was calibrated prior to mobilization in the field and daily operational function checks were performed prior to use. The calibration and function check documentation are included in Appendix B. Based on the highest system background (blank) measurements from daily operational function checks and efficiency (pCi/g/cpm), the highest Ra-226 MDC for the screening system calculated was less than 1.0 pCi/g, significantly less than the 6.8 pCi/g IL. The MDCs during the supplemental characterization met the QA objective.

The QA/QC measures also included twelve field QA/QC duplicate soil samples out of the 58 soil samples collected sent to the off-site vendor laboratory for analysis to confirm contamination relative to the IL levels estimated by the field ex-situ gamma radiation soil screening. The QA/QC duplicate vendor laboratory results are included in Table 3. All QA/QC sample results confirm Ra-226 concentration levels relative to the IL level determined by the field ex-situ gamma radiation soil screening. The Ra-226 concentration in QA/QC duplicate samples estimated by on-sit ex-situ gamma radiation soil screening are comparable to the off-site vendor laboratory analytical results.

Note: Static Gamma Estimated pCi/g levels were estimated from .5" lead collimated detector static gamma measurements.

## Table 5
### Mt. Taylor Mine Site - NCA Soil Radiological Characterization
### Estimated Volumes of Areas above the 6.8 Ra-226 pCi/g Investigation Level

| Estimated Depth of Area > 6.8 Ra-226 pCi/g Investigation Level | Approximate Land Area (acre) | Estimated Volume (cubic yard) |
|---|---|---|
| surface to 6" bgs | 15 | 12,100 |
| surface to 1.0' bgs | 5.2 | 8,067 |
| surface to 1.5' bgs | 0.1 | 242 |
| surface to 2.0' bgs | 0.6 | 1,936 |
| surface to 3.0' bgs | 1.1 | 5,330 |
| surface to 3.5' bgs | 0.1 | 565 |
| surface to 4.5' bgs | 0.9 | 6,534 |
| Estimated Total | 23 | 34,773 |

Note: Does not include volume estimate of the Ore Retnetion Pond dikes. bgs = below ground surface

CAL'D W/ 39" CABLE.

Ludlum Measurements, Inc. certifies that the above instrument has been calibrated by standards traceable to the National Institute of Standards and Technology, or to the calibration facilities of other International Standards Organization members, or have been derived from accepted values of natural physical constants or have been derived by the ratio type of calibration techniques.
All pass/fail determinations are based on the manufacturer's specifications without considering uncertainty factors.
Measurement results represent expanded uncertainties expressed at approximately the 95% level of confidence, using a coverage factor of k=2.
The calibration system conforms to the requirements of ANSI/NCSL Z540-1-1994 and ANSI N323AB-2013

Ludlum Measurements, Inc certifies that the above instrument has been calibrated by standards traceable to the National Institute of Standards and Technology, or to the calibration facilities of other International Standards Organization members, or have been derived from accepted values of natural physical constants or have been derived by the ratio type of calibration techniques.
All pass/fail determinations are based on the manufacturer's specifications without considering uncertainty factors.
Measurement results represent expanded uncertainties expressed at approximately the 95% level of confidence, using a coverage factor of k=2.
The calibration system conforms to the requirements of ANSI/NCSL Z540-1-1994 and ANSI N323AB-2013

The analyses presented in this report were performed by Energy Laboratories, Inc., 2393 Salt Creek Hwy, Casper, WY 82601-9601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the report package. Any issues encountered during sample receipt are documented in the Work Order Receipt Checklist.

The results as reported relate only to the item(s) submitted for testing. This report shall be used or copied only in its entirety. Energy Laboratories, Inc. is not responsible for the consequences arising from the use of a partial report.

Energy Laboratories, Inc. verifies the reported results for the analysis has been technically reviewed and approved for release.

If you have any questions regarding these test results, please contact your Project Manager.

# CASE NARRATIVE

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

BRANCH LABORATORY LOCATIONS
eli-b - Energy Laboratories, Inc. - Billings, MT
eli-g - Energy Laboratories, Inc. - Gillette, WY
eli-h - Energy Laboratories, Inc. - Helena, MT

ISO 17025 DISCLAIMER:
The results of this Analytical Report relate only to the items submitted for analysis.

ENERGY LABORATORIES, INC. - CASPER,WY certifies that certain method selections contained in this report meet requirements as set forth by the above accrediting authorities. Some results requested by the client may not be covered under these certifications. All analysis data to be submitted for regulatory enforcement should be certified in the sample state of origin. Please verify ELI's certification coverage by visiting www.energylab.com

ELI appreciates the opportunity to provide you with this analytical service. For additional information and services visit our web page www.energylab.com.

### Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

The reference date for Radon analysis is the sample collection date. The reference date for all other Radiochemical analyses is the analysis date. Radiochemical precision results represent a 2-sigma Total Measurement Uncertainty.

For methods that require zero headspace or require preservation check at the time of analysis due to potential interference, the pH is verified at analysis. Nonconforming sample pH is documented as part of the analysis and included in the sample analysis comments.

Trip Blanks and/or Blind Duplicate samples are assigned the earliest collection time for the associated requested analysis in order to evaluate the holding time unless specifically indicated.

### Contact and Corrective Action Comments:

None

## 1.0 Introduction and Background

This report provides the results of the South Controlled Area (SCA) Soil Radiologic Characterization (SRC) that was conducted at the Mt. Taylor Mine (Site) in Cibola County, near San Mateo, New Mexico. This SRC was performed to check the status and estimate radiologic contamination in soil that exceeds the Site Radiation Cleanup Criteria (RCC) of 6.8 pCi/g Radium (Ra)-226, which is also used as the Site Investigation Level (IL). The SCA SRC area includes the Borrow Area C, County Road 334, the Service and Support Area, West Offsite Area and the Recognized Data Gap Area, as shown in Figure 1. The Mine Compound Area within the Services and Support Area was previously characterized and was not included in this SRC. The methods and procedures used during this SRC were consistent with the agency approved June 2020 Work Plan for Post-Mining Radiological Surveys of Permit Area and Impacted Lands (Work Plan), and applicable survey methods described in the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM, EPA 2000a). The RCC specified in the March 2016 *Joint Guidance for the Cleanup and Reclamation of Existing Uranium Mining Operations in New Mexico* (EMNRD, 2016) (2016 Guidance) by the Energy, Minerals & Natural Resources Department (EMNRD) and the New Mexico Environment Department (NMED) was used for the SCA SRC investigation level (IL). The Ra-226 cleanup criteria of 5.0 pCi/g above the background level in land averaged over 100 square meters in surface soil (top six inches) specified in the Joint Guidance is taken from the UMTRCA (40 CFR 192) regulation, which is based on an unrestricted land use exposure scenario. Thus, a 6.8 pCi/g Ra-226 IL (5.0 pCi/g plus 1.8 pCi/g background level) has been established for the Site.

The Site was an underground uranium mine located in Cibola County, near San Mateo, New Mexico. The mine was developed by Gulf Mineral Resources Company (Gulf) in the 1970s, and ore production occurred from 1979 to 1982. Following the transfer of the Site to Chevron Resources Company in 1985, the ore production resumed and continued until 1990. Rio Grande Resources (RGR) acquired the Site in 1991. In 1999 the Site entered standby status under Mine Permit C1002RE with EMNRD. On December 29, 2017, the permit changed to an active status, and on December 3, 2019, RGR notified EMNRD of its intentions to begin the Site closeout/closure process.

The following sections describe the strategy, methods and procedures that were used and the results of the SCA SRC conducted at the Site.

## 2.0 Previous Radiologic Characterizations

Surface gamma radiation surveys were performed periodically within operationally controlled areas of the Site, including within the SCA, to monitor changes in radiological conditions during a period of remedial excavations in the Mine Water Treatment Ponds, the construction of the disposal cell, placement of contaminated mine materials, and the gradual removal of ore from the Ore Pad stockpile. The most recent gamma survey conducted in the SCA SRC area prior to this characterization was conducted in March 2020

and showed gamma radiation levels exceeding the 6.8 pCi/g Ra-226 IL in numerous areas within the SCA. The 2020 gamma survey results are summarized in the Work Plan.

## 3.0 Objective of the Soil Radiological Characterization

The Site is a former uranium mine, therefore the surface and subsurface soil is expected to be impacted by radionuclides associated with the uranium decay series, with Ra-226 being the primary Constituent of Concern (COC). The objective of this characterization is to evaluate Ra-226 contamination exceeding the 6.8 pCi/g Ra-226 IL in surface and subsurface soils to facilitate the estimation of the volume of radiologic impacted soil within the SCA SRC area.

## 4.0 Field Investigation

Field investigations for this SCA SRC were conducted consistent with the Work Plan and were performed during the period of April 2025 through September 30, 2025. The field investigation included both 0.5-inch thick lead collimated and bare (uncollimated) 2x2 sodium iodide (NaI) detector Differential Global Positioning System (DGPS) based gamma radiation scan surveys, and measurements. Additionally, static gamma radiation surveys, soil sampling, ex-situ soil screening, and offsite vendor laboratory confirmatory sample analysis were utilized during this SRC. The DGPS based gamma scan surveys were conducted to provide lateral Ra-226 concentration level estimates in surface soils. To assess subsurface radiological contamination, areas of potentially similar vertical extent of contamination were selected based on the DGPS gamma scan surveys data point (DP) locations for static gamma surveys and subsurface soil samples were selected to provide for an areal contamination depth profile estimation. Ex-situ gamma radiation soil screening was performed on the soil samples collected to provide real-time information to estimate surface and subsurface Ra-226 contamination levels. Offsite vender laboratory soil sample analysis was utilized to confirm the contamination levels assessed by the onsite real time ex-situ soil screening.

### 4.1 Surface Gamma Radiation Scan and Static Surveys

The instrument configuration used for direct gamma radiation level measurements during this characterization consisted of 0.5 inch thick lead collimated and bare 2x2 NaI scintillation detectors (Eberline SPA-3 or Ludlum 44-10) coupled to a scaler/rate meter, such as a Ludlum 2221, Ludlum 2241 or Ludlum 3000. This instrument configuration is widely used for this type of survey and is recommended by the MARSSIM. The scaler/rate meters were interfaced with a sub-meter accurate DGPS with surveying software and a data logger/controller for electronically recording the gamma radiation levels to the corresponding geo-location coordinates. The coordinate system used for this work was the State Plane Coordinate System (NAD83, New Mexico West, US Feet) system. The direct gamma radiation surveys using a NaI scintillation detector provides radiation levels in counts per minute (cpm).

During this characterization, systematic gamma radiation scan surveys using bare 2x2 NaI detectors were performed to estimate the level of Ra-226 in surface soil within the characterization areas. Although bare detectors do not avoid lateral gamma radiation shine, bare detectors have a large field of view and provide a large scan coverage area for an efficient and conservative lateral extent of contamination assessment. To better characterize the surface soil and to assist in the selection of data point locations, the surface gamma scan survey was performed at a higher density, 25-feet transect spacing, compared to the March 2020 scan density of about 60-ft transect spacing. Based on a conservative field of view (FOV) of about ten feet diameter for a bare 2x2 NaI detector for Ra-226 gamma radiation, scanning transects spacing of 25 feet would provide at least a 40% scan coverage, which is sufficient to identify and characterize any surface soil contamination. Twenty-five feet spaced geo-projected transects within the SCA were digitally created using a mapping software and loaded on the field data logger/controller. The gamma scan survey was performed by scanning along these transects with the detector at 12 inches above the ground surface at a scan rate of about three feet per second, with a data collection time interval of two seconds. A Bare detector gamma scan survey was performed in areas away from the Ore Pad, which could result in lateral gamma radiation shine. In areas located near the Ore Pad, a 0.5 inch thick lead collimated detector was used to mitigate lateral gamma radiation shine. The bare/collimated detector gamma scan boundary is shown in Figure 2.

The geo-located gamma scan data includes the gamma scan point ID number, date and time, location coordinates, and detector cpm. The scan data was exported from the data logger and the bare detector cpm were converted to equivalent Ra-226 estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0005 x CPM)-7.32 $R^2$ = 0.97). The collimated detector cpm data was converted to equivalent Ra-226 pCi/g estimate using the Site-specific correlation (Ra-226 pCi/g = 0.0016 x CPM)-7.5 $R^2$ = 0.83). The 20,357 discrete gamma scan points collected during the gamma scan survey were exported from the scan system and the detector cpm data was converted into the equivalent estimated surface soil Ra-226 pCi/g concentration using the appropriate Site-specific correlation. The data was then plotted using a mapping software, shown in Figure 2, and arranged in graduated color ranges, then reviewed to identify areas that exceeded the Ra-226 IL. A typical gamma scan data export table from the scan system data logger and estimated Ra-226 concentration calculated using the correlation equation is shown in Table 1. Gamma scan survey data collected during this characterization are provided in an electronic file.

As previously discussed, areas of potentially similar vertical extent of contamination were selected based on the DGPS gamma scan surveys. A total of 49 data point locations (shown in Figure 3) were selected within these areas for the estimation of the vertical extent of Ra-226 contamination above the Site IL. A one-minute collimated detector static gamma radiation survey was performed at each data point location to estimate the surface soil Ra-226 levels prior to test pit excavation or collecting of any soil samples.

### 4.2 Soil Sampling and Ex-Situ Gamma Radiation Soil Screening

Two data point locations (DP-01 and DP-02) were selected on the southeast edge of Borrow Area C to verify surface soil Ra-226 levels where the gamma scan survey data showed Ra-226 concentrations slightly above

the IL, which was suspected to be due to lateral gamma shine from the nearby Ore Pad Area. Subsurface soil sampling was performed at these two locations. Additionally, data point locations DP-3 and DP-14 were selected at locations where the gamma scan survey data showed an isolated area with Ra-226 levels slightly above the IL. The locations were visually inspected and a one-minute collimated detector static gamma measurement was performed at each location to determine if subsurface soil sampling was necessary. The survey data was recorded on Static Gamma Radiation Survey Forms, which are included in Appendix A. The collimated detector measurements were converted to soil Ra-226 concentrations using the correlation equation for the collimated detector. The static gamma survey results are summarized in Table 2.

Soil sampling and on-Site ex-situ gamma radiation soil screening were performed during July 2025 to September 2025 to estimate the subsurface soil Ra-226 contamination exceeding the IL. Surface (0 to 6 inches) soil samples were not collected at every data point location during this characterization. The estimated surface soil Ra-226 level was determined from one-minute collimated detector static gamma radiation surveys. A one-minute collimated detector static gamma radiation survey provides a significantly higher certainty for a surface soil Ra-226 estimate than a two second integration gamma radiation scan survey provides. Additionally, the use of a collimated detector mitigates any lateral gamma radiation shine interference from any nearby elevated concentration areas.

Ex-situ gamma radiation soil screening was conducted to provide a real-time estimate of Ra-226 concentrations in soil samples to determine the depth at which subsurface soil sampling is no longer necessary. This method is more reliable than in-situ direct gamma radiation level measurements and allows for a more reliable real-time Ra-226 concentration assessment. The on-site ex-situ soil screening method consists of selectively measuring the 609 KeV region gamma radiation of Bi-214, a decay product of Ra-226. A single channel analyzer (Ludlum L2221 or Ludlum 3003) integrated with a Ludlum 44-20 3x3 NaI scintillation detector was used to measure the 609 keV energy peak region of Bi-214. A homogenized soil sample was placed around the plastic lined detector in a heavily lead shielded counting chamber. The use of a heavily shielded counting chamber lowers the system background counts, thus, improving the system's minimum detectable concentration (MDC). A reference soil with aRa-226 concentration of 6.6 pCi/g, comparable to the 6.8 pCi/g IL, was prepared and was used for soil screening during this SRC. The 6.6 pCi/g reference soil provides a conservative estimate of the Ra-226 concentration in samples below the IL.

Subsurface soil samples were collected from each of the 49 data point locations. The number and depth of the samples at each data point location varied depending upon location and soil screening results. A backhoe was used to excavate a test pit trench for subsurface soil sample collection at data point location where subsurface soil samples were necessary for depth characterization. The test pit trenches were excavated using a backhoe in approximately 6 to 12 inches depth intervals, depending on the soil type/consistency, visual observations, and/or gamma radiation level measurements. At each interval, a subsurface soil sample was collected from the base of the excavation for ex-situ gamma radiation soil screening. Stainless steel sampling trowels, bowls and #25 sieve as needed were used to collect the soil samples. The excavation continued until on-site ex-situ gamma radiation soil screening indicated that Ra-

226 concentrations were below the 6.8 pCi/g IL. At an isolated data point location DP-40, a surface static gamma measurement showed Ra-226 levels at approximately 25 pCi/g. Upon inspection, a single mine waste rock was observed partially buried at the data point location. The mine waste rock was removed and the subsequent surface static gamma remeasurement showed Ra-226 levels below the IL. Therefore, test pit trench excavation and subsurface soil sampling was not necessary at this data point location. The soil sample logs and the field soil screening forms are included in Appendix A. The ex-situ gamma radiation screening data is summarized in Table 3, and includes estimated Ra-226 concentrations of the samples relative to the 6.8 pCi/g IL. The surface and subsurface soil sampling Ra-226 levels above the IL depth results are summarized in Table 4.

At 39 of the 49 data point locations, a 6-12 inch below ground surface (bgs) subsurface soil sample was collected and ex-situ soil gamma screened. Furthermore, at 18 of those 39 data point locations, a subsurface soil sample at a depth of 1-2 feet bgs was collected and ex-situ soil screened since the 6–12-inch bgs subsurface sample soil screening result was above the IL. Subsurface soil samples from 15 data point locations were collected at a depth of 2-3 feet bgs since the shallower subsurface sample screening result was above the IL. Subsurface soil samples from eight data point locations were collected at a depth of 3-4 feet bgs since the shallower subsurface sample screening result was above the IL. At three data point location within the Service and Support Area, DP-30, DP-31, and DP-32, subsurface soil samples were collected at a depth greater than four feet since the shallower subsurface sample screening result was above the IL.

At data point location DP-41 which is located along the SCA fence and the Southern Diversion Channel at the southwest corner of the Services and Support Area, subsurface soil sampling was halted as the soil had low cohesion causing continual trench collapse past four feet bgs, even though the Ra-226 level at this depth was above the IL. Observations of the area made during excavation indicate that backfilling in this small area is likely to be as deep as ten feet bgs. At data point DP-29, a concrete slab was encountered at 3.7 feet bgs. Surface static gamma measurements and sample screening of the subsurface soil determined that the soil from the surface to 3.7 feet contained Ra-226 levels above the IL. An additional test pit trench was excavated approximately 10 feet east of DP-29 and the concrete slab was encountered at the same depth. Upon further discussion with Site staff, DP-29 was in an area where there was a Services and Support Area building that was decommissioned and the concrete slab foundation was left in place. At data point DP-32, located just east of the repository, soil screening determined that the subsurface soil sample from 10 feet bgs was above the IL. However, test pit trench excavation was halted due to backhoe excavation depth limitations. Discussions with Site staff indicated that the waste rock material and debris backfill in this area could be as deep as 25 to 30 feet bgs as this was the historic location of a pond. The exact dimensions of the historic pond are not known. At data point DP-31 in the Services and Support Area, test pit trench excavation continued past 5.5 feet bgs even though the 5.0 to 5.5 feet depth subsurface sample screening showed Ra-226 levels below the IL due to the presence of mine waste debris (timber, loose wires, metal parts/debris, etc.) to about ten feet bgs.

Although the primary objective of the ex-situ gamma radiation soil screening was to determine the Ra-226 concentrations above or below the 6.8 pCi/g IL, Ra-226 concentrations were estimated in all soil samples collected and screened. A correlation calibration of the ex-situ soil screening system was performed using a 6.6 pCi/g, a 25 pCi/g, and a 50 pCi/g reference soil. This correlation was updated with offsite vendor laboratory soil sample results for the samples that were screened onsite and sent to the laboratory for QA/QC confirmation. This updated correlation is included in Appendix B. The estimated Ra-226 concentrations calculated using the updated correlation regression equation [Ra-226 pCi/g = (CPM x 0.0144) – 2.55, $R^2$ = 0.995] of the subsurface soil samples are included in Tables 3 and 4.

A total of 45, which included five field quality assurance/quality check (QA/QC) duplicates, of the soil samples that were ex-situ gamma radiation soil screened on-site were sent to an offsite vendor laboratory for analysis (Energy Laboratories, in Casper, WY). These soil samples were analyzed for Ra-226 using EPA Method 901.1 (modified for soil matrix) for confirmation of the on-site ex-situ soil screening results. The laboratory results report is included in Appendix C and are summarized in Table 3. As shown in Table 3, the estimated Ra-226 levels determined by the on-site ex-situ soil screening are comparable with the vendor laboratory Ra-226 results, specifically in regards to determining that the Ra-226 levels are above or below the IL.

### 4.3 South Controlled Area Characterization Summary

As described previously, this SCA SRC included the areas shown in Figure 1. The entire SCA SRC area consists of approximately 111 acres. The Borrow Area C, in which only surface soil was characterized by scan gamma survey during this SRC, consists of approximately 12 acres. The SCA soil in approximately a 91 acres area is below the 6.8 pCi/g Ra-226 IL. In the remaining approximately 20 acre SCA area, the soil exceeds the IL and ranges from the ground surface to a depth of ten feet bgs. The depth of soil exceeding the IL at each data point is summarized in Table 4 and shown in Figure 4. Figure 5 shows areas within the SCA SRC with soil exceeding the IL at various contamination depths. The areas and conservative planning-level estimated volume of in-situ soil exceeding the IL within this characterization area are summarized in Table 5. The excavated volume of soil exceeding the IL may be higher than the estimated in-situ volume due to soil swell factor and the excavation equipment and technique used.

#### 4.3.1 Borrow Area C Surface Soil Characterization Summary

Borrow Area C consists of approximately 12 acres and is located north of the SCA, as shown in Figure 1. The initial SRC in Borrow Area C consisted of a gamma scan survey to confirm whether the borrow material is near the Ra-226 background level. As shown in Figure 2, the gamma scan survey showed Ra-226 levels below the IL in Borrow Area C, except for a small area in the southeast corner where the gamma scan survey showed Ra-226 levels just above the IL, likely due to lateral gamma radiation shine from the nearby North Control Area/Ore Pad Area. Static gamma measurements with a collimated detector and surface soil samples were collected at two data point locations (DP-01 and DP-02) in this area to confirm if the elevated

gamma readings are a result of lateral gamma radiation shine influence. The static gamma measurements data, the on-Site soil screening results and the offsite vendor laboratory soil sample result, shown in Table 2 and Table 3 respectively, confirm that the elevated gamma scan measurements were due to the influence of lateral gamma radiation shine, and that Ra-226 levels in the surface soil in Borrow Area C is well below the IL.

### 4.3.2 County Road 334 Area Characterization Summary

The County Road 334 Area, shown in Figure 1, was included in this SRC due to the results of the 2020 gamma scan showing elevated gamma radiation levels throughout the area. As part of this SRC, a gamma scan survey within the County Road 334 Area was conducted using a 0.5-inch lead collimated detector to mitigate any gamma radiation shine from the adjacent SCA and NCA areas that have significantly elevated gamma radiation levels. As shown in Figure 2, approximately 4 acres of the County Road 334 area is above the IL, which is a significant portion of the total area (≈7 acres) of the County Road 334 Area. As shown in Table 4 and Figure 5, the depth of soil exceeding the IL ranged from 0.5 feet to 2 feet in this area.

### 4.3.3 West Data Gap Area Characterization Summary

A gamma scan survey at 25 feet transect spacing was conducted in the West Gap Area, shown in Figure 1, during this SRC since the 2020 gamma survey showed several small and one larger sized isolated area with gamma levels potentially exceeding the IL. The West Gap Area consists of approximately 16 acres. Data points DP-14, DP-15 and DP16 were located on three small isolated areas along the northern boundary of the area that potentially exceeded the IL. Data point DP-18, which is located on an isolated area exceeding the IL along the eastern edge of the area. Each of these four small isolated areas were less than 800 square feet. One data point, DP-17, was located within a larger sized area (approximately 6000 square feet) discussed above. After investigation, gamma measurements, subsurface soil sampling and onsite soil screening, data point locations DP-14 and DP-15 were determined to be surface contamination from loose mine waste rock piles, while data point locations DP-16, DP-17 and DP-18 have soil that exceeds the IL at a depth of 0.5 feet bgs.

### 4.3.4 Service and Support (Mine Compound) Area Characterization Summary

The Service and Support Area, as shown in Figure 1, consists of approximately 36.55 acres. A portion of the Services and Support Area designated as the Mine Compound Area was previously characterized in 2023. The Service and Support Area include the Chiller Bench Area and the areas around the hoist house, the service building, the core storage building, the south stock tank, and the carpenter shop, among others The SRC gamma scan survey identified approximately 15 acres of impacted soils above the IL in the Service and Support SRC Area. Impacted soils exceeding the Ra-226 were identified ranging in depths bgs from surface to greater than 10 feet bgs. In the area near and around DP-29, DP-30 and DP-31 impacted soils exceeding the IL depth were observed at approximately 5 feet bgs. At data point location DP-32, soil exceeding the IL

is greater than 10 feet bgs, as discussed in section 4.2. In the area near DP-26 and DP-27 near the Guard House just west of the large-scale soil exceeding the IL was observed up to a one-foot bgs. In the northern portion of the Service and Support Area, most of the soil exceeding the IL is approximately 0.5 feet bgs, except for a low area with constructed berms near the historic Ore Storage area. The soil impacted above the IL in this pond area was assessed to be up to one-foot bgs. Soil exceeding the Ra-226 IL in the Chiller Bench Area ranged from 0.5 to one-foot bgs. On the Chiller Bench Area is a concrete pad with perimeter walls approximately 8 inches tall that served as a foundation/apparent spill catch basin for the mine water chilling process. Gamma radiation levels measured on this concrete pad were extremely elevated (up to 800,000 cpm). It is not known whether soils below this concrete pad exceeds the IL. An earthen berm with a height varying of one to two feet along the western edge of the Chiller Bench Area is mostly comprised of soil exceeding the IL, as shown in Figure 2.

### 4.3.5 East Data Gap Area Characterization Summary

The East Gap Area shown in Figure 1 consists of approximately 40 acres of which most of the area was not expected to contain soils that exceeded the IL as historic mining operations were not conducted throughout the entire area. For this SRC, a gamma scan survey was performed on roads, road shoulders, and berms, around infrastructures, on visibly disturbed areas and on areas that were discovered to have historic mining activities to assess surface soil contamination and potential impacted subsurface soils exceeding the Ra-226 IL. The gamma scan survey identified approximately 0.5 acres of impacted soils exceeding the IL. Most locations where soil exceeding the IL was observed, the depth of soil above the IL was at 6 inches bgs. At data point location DP-49, the depth bgs was observed at 6 inches, however this location was located on a 2.5 feet tall earthen berm. A portion of this 2.5 feet tall berm approximately 10 feet in length had soil exceeding the IL. The depth of soil exceeding the IL at data point location DP-47, which was located within a low area with constructed berms, was observed at greater than 4 feet bgs and includes the entire northern portion of the pond floor and berm. Test Pit trench excavation at this location was halted as the surrounding soil had low cohesion causing the trench to continually cave-in. Mine waste rock and debris were observed at all depths of excavation.

## 5.0 Soil Sampling and Analysis

Soil samples collected during the SCA SRC for on-site ex-situ gamma radiation soil screening were collected consistent with the Work Plan. Field QA/QC duplicate samples were ex-situ gamma radiation soil screened at a frequency of 10% of the total number of soil samples screened. A total of 98 surface and subsurface soil samples were collected for the SCA characterization. The test pit trenches were excavated using a backhoe at approximately 6 to 12 inches depth intervals depending on soil type and visual observations. At each interval, a subsurface soil sample was collected if deemed necessary from the base of the excavation for ex-situ gamma radiation soil screening. Field sampling equipment used for soil sampling included: stainless steel scoops, hand auger, bowls, sieve, and spoons that were decontaminated between sample locations. The soil sampling equipment decontamination was conducted by brushing off loose

visible soil and when necessary was rinsed with distilled water, then wiped with clean towels. The rinsed water was disposed of in Active Pond No. 2. Excavator buckets were cleaned by removing any loose, visible soil. Any soils excavated from the test pits were returned to the test pit excavations from which the soil came. Personal protection equipment (PPE), such as gloves, were brushed off and scanned for residual contamination and were disposed of.

Subsurface soil samples were analyzed by on-site ex-situ gamma radiation soil screening to provide real time assessment of Ra-226 level above or below the IL. A QA/QC confirmatory subsurface soil sample from each test pit from at the depth which screened below the IL was sent to an offsite Vendor laboratory. A total of thirty-nine QA/QC confirmatory soil samples, plus five QA/QC field duplicate samples were placed in labeled Ziploc bags and packaged along with a completed chain of custody in a cooler with a custody sealed lid and shipped to Energy Laboratories, Inc for Ra-226 analysis. The soil samples were analyzed for Ra-226 with a reporting limit of 0.5 pCi/g, using EPA Method 901.1 (modified for soil matrix). The completed chain of custody and the analytical results are included in Appendix C.

## 6. 0 Quality Assurance and Quality Control Measures

QA/QC measures were implemented during this characterization to ensure that decisions were made based on data of acceptable quality. All radiologic survey instruments have been calibrated at least annually. Additionally, operational functions checks were performed on all radiologic instruments daily prior to use. The calibration and function check documents are included in Appendix B. During this characterization, no instruments were found to be out of calibration or inoperable as indicated by the operational function checks. The instrument background measurements for bare 2x2 NaI detectors during daily operational function checks were less than 10,000 cpm as shown in Appendix B. The bare detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of at least six feet diameter. The 2x2 NaI detector response factor is determined to be 0.0005 pCi/g/cpm from the linear regression for the Site-specific correlation included in Appendix B. Based on the above detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a scan survey at a scan speed of three feet per second, calculated using MARSSIM guidance, were less than 1.0 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The instrument background measurements for the 0.5 inch thick lead collimated 2x2 NaI detectors during daily operational function checks were less than 3,200 cpm, as shown in Appendix B. The collimated detector field of view (FOV) at 12 inches above the ground surface is conservatively assumed at an area of approximately 1.5 feet diameter. The collimated 2x2 NaI detector response factor is determined to be 0.0016 pCi/g/CPM from the linear regression for the Site-specific correlation included in Appendix B. Based on the above collimated detector parameters, the Ra-226 minimum detectable concentrations (MDCs) for a one minute static survey, calculated using MARSSIM guidance, was less than 0.5 pCi/g, which is significantly below 50% of the 6.8 pCi/g IL. The ex-situ soil gamma radiation screening system was calibrated prior to mobilization in the field and daily operational function checks were performed prior to use. The calibration and function check documentation are included in Appendix B. Based on the highest system background (blank) measurements from daily operational function checks and efficiency (pCi/g/cpm), the

highest Ra-226 MDC for the screening system calculated was less than 1.0 pCi/g, significantly less than the 6.8 pCi/g IL. The MDCs during the supplemental characterization met the QA objective.

The QA/QC measures also included five field QA/QC duplicate soil samples out of the 45 soil samples collected sent to the off-site vendor laboratory for analysis to confirm contamination relative to the IL levels estimated by the field ex-situ gamma radiation soil screening. The QA/QC duplicate vendor laboratory results are included in Table 3. All QA/QC sample results confirm Ra-226 concentration levels relative to the IL level determined by the field ex-situ gamma radiation soil screening. The Ra-226 concentration in QA/QC duplicate samples estimated by on-sit ex-situ gamma radiation soil screening are comparable to the off-site vendor laboratory analytical results.

Note: Static Gamma Estimated pCi/g levels were estimated from .5" lead collimated detector static gamma measurements.

## Table 5
### Mt. Taylor Mine Site - SCA Soil Radiological Characterization
### Estimated Volumes of Areas above the 6.8 Ra-226 pCi/g Investigation Level

| Estimated Depth of Area > 6.8 Ra-226 pCi/g Investigation Level | Approximate Land Area (acre) | Estimated Volume [1] (cubic yard) |
|---|---|---|
| surface to 6" bgs | 14 | 11,300 |
| surface to 1.0' bgs | 3.0 | 4,900 |
| surface to 2.0' bgs | 0.5 | 1,620 |
| surface to 2.5' bgs | 0.01 | 40 |
| surface to >4.0' bgs [2] | 0.2 | 1,300 |
| surface to 5.0' bgs | 2.0 | 4,900 |
| surface to >10.0' bgs [2] | 1.0 | 2,500 |
| Estimated Total | 21 | 26,560 |

Note (1): Estimates are based on area historic Site use, observed waste and debris and excavation depth. Estimated volumes represent planning-level estimates and are not final excavation quantities.
Note (2): For the depths >4.0' and >10.0" bgs the estimated volume is an estimated minimum volume.

**COMMENTS:**
See attachments for all other settings.

Det1. set up for gamma detector.

Det2. set up for typical M44-7.

Ludlum Measurements, Inc. certifies that the above instrument has been calibrated by standards traceable to the National Institute of Standards and Technology.
The pass/fail tolerance of 10% (unless otherwise noted) is based on the manufacturer's specifications without considering uncertainty factors.
Measurement results represent expanded uncertainties expressed at approximately the 95% level of confidence, using a coverage factor of k=2.
Measurement Uncertainties: Voltage measurements 1.4%, Gamma Exposure/Dose 5.6%, Neutron Dose 7.0%, Count rate 5.2%.
The calibration system conforms to the requirements of ANSI/NCSL Z540-1-1994 and ANSI N323AB-2013.

The analyses presented in this report were performed by Energy Laboratories, Inc., 2393 Salt Creek Hwy, Casper, WY 82601-9601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the report package. Any issues encountered during sample receipt are documented in the Work Order Receipt Checklist.

The results as reported relate only to the item(s) submitted for testing. This report shall be used or copied only in its entirety. Energy Laboratories, Inc. is not responsible for the consequences arising from the use of a partial report.

Energy Laboratories, Inc. verifies the reported results for the analysis has been technically reviewed and approved for release.

If you have any questions regarding these test results, please contact your Project Manager.

# LABORATORY ANALYTICAL REPORT

Prepared by Casper, WY Branch

**Client:** Rio Grande Resources Corporation
**Project:** MTM SCA Characterization
**Lab ID:** C25090418-001
**Client Sample ID:** DP-30 [4.5-6.0]

**Report Date:** 10/16/25
**Collection Date:** 08/21/25 10:35
**DateReceived:** 09/10/25
**Matrix:** Soil

| Analyses | Result | Units | Qualifiers | RL | MCL/ QCL | Method | Analysis Date / By |
|---|---|---|---|---|---|---|---|
| **RADIONUCLIDES, GAMMA** | | | | | | | |
| Radium 224 | 0.8 | pCi/g-dry | U | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 224 precision (±) | 2.8 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 224 MDC | 4.7 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 226 | 2.4 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 226 precision (±) | 0.3 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 226 MDC | 0.3 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 228 | 1.7 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 228 precision (±) | 0.5 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |
| Radium 228 MDC | 0.5 | pCi/g-dry | | | | E901.1M | 10/08/25 13:39 / haw |

**Report Definitions:**
RL - Analyte Reporting Limit
QCL - Quality Control Limit
U - Not detected
MCL - Maximum Contaminant Level
ND - Not detected at the Reporting Limit (RL)

| Water - pH acceptable upon receipt? | Yes ☐ | No ☐ | Not Applicable ☑ |

### Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

The reference date for Radon analysis is the sample collection date. The reference date for all other Radiochemical analyses is the analysis date. Radiochemical precision results represent a 2-sigma Total Measurement Uncertainty.

For methods that require zero headspace or require preservation check at the time of analysis due to potential interference, the pH is verified at analysis. Nonconforming sample pH is documented as part of the analysis and included in the sample analysis comments.

Trip Blanks and/or Blind Duplicate samples are assigned the earliest collection time for the associated requested analysis in order to evaluate the holding time unless specifically indicated.

### Contact and Corrective Action Comments:

None

The analyses presented in this report were performed by Energy Laboratories, Inc., 2393 Salt Creek Hwy, Casper, WY 82601-9601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the report package. Any issues encountered during sample receipt are documented in the Work Order Receipt Checklist.

The results as reported relate only to the item(s) submitted for testing. This report shall be used or copied only in its entirety. Energy Laboratories, Inc. is not responsible for the consequences arising from the use of a partial report.

Energy Laboratories, Inc. verifies the reported results for the analysis has been technically reviewed and approved for release.

If you have any questions regarding these test results, please contact your Project Manager.

| Water - pH acceptable upon receipt? | Yes ☐ | No ☐ | Not Applicable ☑ |

### Standard Reporting Procedures:

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

The reference date for Radon analysis is the sample collection date. The reference date for all other Radiochemical analyses is the analysis date. Radiochemical precision results represent a 2-sigma Total Measurement Uncertainty.

For methods that require zero headspace or require preservation check at the time of analysis due to potential interference, the pH is verified at analysis. Nonconforming sample pH is documented as part of the analysis and included in the sample analysis comments.

Trip Blanks and/or Blind Duplicate samples are assigned the earliest collection time for the associated requested analysis in order to evaluate the holding time unless specifically indicated.

### Contact and Corrective Action Comments:

The temperature of the sample(s) in shipping container 1 was 22.7°C and shipping container 2 was 21.5°C. DRS 09/29/25

## MT TAYLOR MINE SHAFT MUCK SAMPLE LOCATIONS – 5/18/2010

Bulk samples of shaft muck from Mt. Taylor Mine waste rock pile collected on 5/18/2012 by Alan Kuhn. Locations are approximate (+/- 50 ft) based on visual reference to slopes. Splits delivered 5/18/12 to Kleinfelder Albuquerque for grain size analysis and plasticity tests. Other splits left with RGR Mine office for shipment to Energy Labs for testing of U and Ra concentration.

Notes:
bgs = below ground surface
mg/Kg = milligrams per killogram
DAF=Dilution Attenuation Factor
NA = No DAF values available, NMED 2012, rev6

Total metals concentrations should be compared to background soil sample concentrations before comparing to Soil Screening Levels (SSL). Only metal concentrations above background should be considered for comparison to SSLs.
NMED considers a DAF=20 to be protective of groundwater for a 0.5-acre source. SSL values are included for reference only, as they are applicable for reclamation, not for mines that are active or on stand-by status.
B = The analyte was detected in the method blank.
D = Reporting limit increased due to sample matrix.
U = Not detected at minimum detectable concentration.

# ANALYTICAL SUMMARY REPORT

July 05, 2012

Rio Grande Resources Corporation
PO Box 1150
Grants, NM 87020

Workorder No.: C12040804 Quote ID: C3778 - Mt Taylor Mine Closure Plan

Project Name: Mt. Taylor Mine Closure Plan

Energy Laboratories, Inc. Casper WY received the following 37 samples for Rio Grande Resources Corporation on 4/13/2012 for analysis.

# ANALYTICAL SUMMARY REPORT

The results as reported relate only to the item(s) submitted for testing. The analyses presented in this report were performed at Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Radiochemistry analyses were performed at Energy Laboratories, Inc., 2325 Kerzell Lane, Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

If you have any questions regarding these test results, please call.

Report Approved By:

**CLIENT:** Rio Grande Resources Corporation
**Project:** Mt. Taylor Mine Closure Plan
**Sample Delivery Group:** C12040804

**Revised Date:** 07/05/12
**Report Date:** 06/13/12

# CASE NARRATIVE

REVISED/SUPPLEMENTAL REPORT
The attached analytical report has been revised from a previously submitted report due to the request by the client for the analysis of Radium 226 and Radium 228 on the Sediment on all samples and Chloride and Sulfate on the Sediment on samples -013 through -020 and -024 through -027. The data presented here is from that analysis.

PREP COMMENTS
The prep hold time for Mercury analysis was exceeded by up to 10.2 days.
The prep hold time for Chloride and Sulfate analysis was exceeded by 38.8 days.

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

BRANCH LABORATORY LOCATIONS
eli-b - Energy Laboratories, Inc. - Billings, MT
eli-g - Energy Laboratories, Inc. - Gillette, WY

ISO 17025 DISCLAIMER:
The results of this Analytical Report relate only to the items submitted for analysis.

ENERGY LABORATORIES, INC. - CASPER,WY certifies that certain method selections contained in this report meet requirements as set forth by the above accrediting authorities. Some results requested by the client may not be covered under these certifications. All analysis data to be submitted for regulatory enforcement should be certified in the sample state of origin. Please verify ELI's certification coverage by visiting www.energylab.com

ELI appreciates the opportunity to provide you with this analytical service. For additional information and services visit our web page www.energylab.com.

**Report Definitions:**
RL - Analyte reporting limit.
QCL - Quality control limit.
MDC - Minimum detectable concentration
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
B - The analyte was detected in the method blank.
U - Not detected at minimum detectable concentration

**Report Definitions:**
RL - Analyte reporting limit.
QCL - Quality control limit.
MDC - Minimum detectable concentration
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
B - The analyte was detected in the method blank.

**Report Definitions:**
RL - Analyte reporting limit.
QCL - Quality control limit.
MDC - Minimum detectable concentration
D - RL increased due to sample matrix.
MCL - Maximum contaminant level.
ND - Not detected at the reporting limit.
B - The analyte was detected in the method blank.
U - Not detected at minimum detectable concentration

**Qualifiers:**

RL - Analyte reporting limit.

MDC - Minimum detectable concentration

ND - Not detected at the reporting limit.

N - The analyte concentration was not sufficiently high to calculate a RPD for the serial dilution test.

S - Spike recovery outside of advisory limits.

# Standard Reporting Procedures

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

In certain circumstances, samples submitted to Energy Laboratories, Inc. may be subcontracted to other certified laboratories in order to complete the analysis requested. This serves as notice of this possibility. All sub-contract data will be clearly notated on your analytical report.

# ANALYTICAL SUMMARY REPORT

July 10, 2012

Rio Grande Resources Corporation
PO Box 1150
Grants, NM 87020

Workorder No.: C12041044 Quote ID: C3778 - Mt Taylor Mine Closure Plan

Project Name: Mt. Taylor Mine Closure Plan

Energy Laboratories, Inc. Casper WY received the following 28 samples for Rio Grande Resources Corporation on 4/20/2012 for analysis.

| Sample ID | Client Sample ID | Collect Date | Receive Date | Matrix | Test |
|---|---|---|---|---|---|
| C12041044-001 | MT-1-F (6" B.G.) | 04/10/12 10:45 | 04/20/12 | Sediment | Metals, SPLP Extractable<br>Mercury, SPLP<br>Mercury Analysis Prep<br>Filterability<br>Digestion, Total Metals<br>Digestion For RadioChemistry<br>Radium 226<br>Radium 228<br>SPLP Extraction, Regular |

# ANALYTICAL SUMMARY REPORT

The results as reported relate only to the item(s) submitted for testing. The analyses presented in this report were performed at Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Radiochemistry analyses were performed at Energy Laboratories, Inc., 2325 Kerzell Lane, Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

If you have any questions regarding these test results, please call.

Report Approved By:

**CLIENT:** Rio Grande Resources Corporation
**Project:** Mt. Taylor Mine Closure Plan
**Sample Delivery Group:** C12041044

**Revised Date:** 07/10/12
**Report Date:** 06/13/12

# CASE NARRATIVE

REVISED/SUPPLEMENTAL REPORT
The attached analytical report has been revised from a previously submitted report due to the request by the client for the analysis of Radium 226 and Radium 228 on the Sediment on all samples and Chloride and Sulfate on the Sediment on samples -004 through -005, -010 through -016, and -028. The data presented here is from that analysis.

PREP COMMENTS
The prep hold time for the SPLP extraction was exceeded by up to 6 days.
The prep hold time for Chloride and Sulfate analysis was exceeded by 39 days.

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

BRANCH LABORATORY LOCATIONS
eli-b - Energy Laboratories, Inc. - Billings, MT
eli-g - Energy Laboratories, Inc. - Gillette, WY

**Qualifiers:**

RL - Analyte reporting limit.

MDC - Minimum detectable concentration

S - Spike recovery outside of advisory limits.

ND - Not detected at the reporting limit.

N - The analyte concentration was not sufficiently high to calculate a RPD for the serial dilution test.

ND - Not detected at the reporting limit.

# Standard Reporting Procedures

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

# ANALYTICAL SUMMARY REPORT

July 05, 2012

Rio Grande Resources Corporation
PO Box 1150
Grants, NM 87020

Workorder No.: C12050924

Project Name: Mt. Taylor Mine

Energy Laboratories, Inc. Casper WY received the following 3 samples for Rio Grande Resources Corporation on 5/24/2012 for analysis.

| Sample ID | Client Sample ID | Collect Date | Receive Date | Matrix | Test |
|---|---|---|---|---|---|
| C12050924-001 | MT-WP-SM1 | 05/18/12 9:30 | 05/24/12 | Soil | Digestion For RadioChemistry<br>Radium 226<br>Uranium, Isotopic |
| C12050924-002 | MT-WP-SM2 | 05/18/12 9:40 | 05/24/12 | Soil | Same As Above |
| C12050924-003 | MT-WP-SM3 | 05/18/12 10:00 | 05/24/12 | Soil | Same As Above |

The results as reported relate only to the item(s) submitted for testing. The analyses presented in this report were performed at Energy Laboratories, Inc., 2393 Salt Creek Hwy., Casper, WY 82601, unless otherwise noted. Radiochemistry analyses were performed at Energy Laboratories, Inc., 2325 Kerzell Lane, Casper, WY 82601, unless otherwise noted. Any exceptions or problems with the analyses are noted in the Laboratory Analytical Report, the QA/QC Summary Report, or the Case Narrative.

If you have any questions regarding these test results, please call.

**Report Date:** 07/05/12

# CASE NARRATIVE

ORIGINAL SAMPLE SUBMITTAL(S)
All original sample submittals have been returned with the data package.

SAMPLE TEMPERATURE COMPLIANCE: 4°C (±2°C)
Temperature of samples received may not be considered properly preserved by accepted standards. Samples that are hand delivered immediately after collection shall be considered acceptable if there is evidence that the chilling process has begun.

GROSS ALPHA ANALYSIS
Method 900.0 for gross alpha and gross beta is intended as a drinking water method for low TDS waters. Data provided by this method for non potable waters should be viewed as inconsistent.

RADON IN AIR ANALYSIS
The desired exposure time is 48 hours (2 days). The time delay in returning the canister to the laboratory for processing should be as short as possible to avoid excessive decay. Maximum recommended delay between end of exposure to beginning of counting should not exceed 8 days.

SOIL/SOLID SAMPLES
All samples reported on an as received basis unless otherwise indicated.

ATRAZINE, SIMAZINE AND PCB ANALYSIS
Data for PCBs, Atrazine and Simazine are reported from EPA 525.2. PCB data reported by ELI reflects the results for seven individual Aroclors. When the results for all seven are ND (not detected), the sample meets EPA compliance criteria for PCB monitoring.

SUBCONTRACTING ANALYSIS
Subcontracting of sample analyses to an outside laboratory may be required. If so, ENERGY LABORATORIES will utilize its branch laboratories or qualified contract laboratories for this service. Any such laboratories will be indicated within the Laboratory Analytical Report.

MDC - Minimum detectable concentration

ND - Not detected at the reporting limit.

U - Not detected at minimum detectable concentration

# Standard Reporting Procedures

Lab measurement of analytes considered field parameters that require analysis within 15 minutes of sampling such as pH, Dissolved Oxygen and Residual Chlorine, are qualified as being analyzed outside of recommended holding time.

Solid/soil samples are reported on a wet weight basis (as received) unless specifically indicated. If moisture corrected, data units are typically noted as –dry. For agricultural and mining soil parameters/characteristics, all samples are dried and ground prior to sample analysis.

## 1.0 INTRODUCTION

This plan, part of the Closeout/ Closure Plan (CCP) for the Mt. Taylor Mine, describes the measures that Rio Grande Resources (RGR) will take to re-establish vegetation on disturbed areas within the mine permit area that will minimize additional disturbance, mitigate impacts to affected environmental resources, rehabilitate disturbed areas to support post-mining land use (PMLU) of grazing, and provide protection of soil and runoff comparable to the natural conditions in the local area. The requirements of this Plan will be implemented primarily by a contractor at the time of mine closeout. The mine surface facilities are located on 285.6 acres, of which approximately 148 acres are currently disturbed land, and the remaining 137.9 acres are undisturbed. Closeout activities are anticipated to disturb an additional 27 acres, bringing the total land disturbance to 175 acres. Affected areas, to be identified before RGR commences final reclamation, will also be revegetated according to this plan. The affected areas known at this time to be revegetated include Borrow Area B and the areas of the Treated Water Discharge Pipeline outside of the Right-of-Way.

The areas to be revegetated include:

- Support (Service and Support) Facilities – 32 acres
- Mine Water Treatment Area - 28 acres
- Treated Water Discharge Pipeline beyond the mine surface area - 15 acres
- Ore Stockpile Pad and Runoff Retention Pond – 11.8 acres
- Expanded Disposal Cell - 13 acres
- Affected Areas
    - Borrow Area B (and access road) – 6.7 acres
    - Continental Divide Substation Area (depending on the Utility's wishes)
    - County Road 334 - 4.7 acres (non-driving surfaces of the Access Road)
    - Area of the Treated Water Discharge Pipeline outside of the Right-of-Way

The remainder of the disturbed area not to be revegetated includes the Continental Divide Substation, PMLU buildings, road surfaces, the south storm water pond, diversion channels, and rock slopes.

## 2.0 REVEGETATION PROTOCOLS

Revegetation protocols and performance criteria for Part 5 and Part 6 guidelines from the New Mexico Mining and Minerals Division. The particular guidance relevant to the project are the Self-Sustaining Ecosystem Guideline (December 2022), the Soil and Cover Material Handling and Suitability Guideline, and Revegetation Guideline (December 2022). This revegetation plan includes reasonable considerations growth media, seeding conditions, and site conditions including climate and post-mining use.

### 2.1 Grading

To prepare the mine site ground surfaces for revegetation, mine facilities not preserved for PMLU will be removed (CCP Technical Specification C.2) and the disturbed areas within the mine permit area will be regraded (CCP Section 4.4.7, Finish Grading and CCP Technical Specification C.4), including backfill of mine water treatment pond basins to approximate original grades.

Regraded material will be placed to minimize potential adverse effects to surface water, ground water and natural conditions of areas outside of the mine area. All surfaces will be graded to a final surface configuration which will support the approved post-mining land use, which will be grazing, or where appropriate, commercial. Temporary runoff and erosion controls, specified in the Stormwater Pollution Prevention Plan (SWPPP) will be employed to manage sediment generated during closeout earthwork. Grading operations will be performed by dozers, scrapers, graders or other equipment. An excavator with hydraulic hammer may be used to reduce high walls to 1H:1V slope, where appropriate. Finish grading will create the grades and slope directions shown on the CCP Appendix A drawings sheets CL 07A, CL 07B, CL 14, and CL 15, which may include shallow depressions and will have a roughened surface suitable for seed nesting and resistance to erosion.

### 2.2 Growth Media Considerations

At the Mt. Taylor Mine, the soil profile is typically 0-36 inches of silty sand over layers of interbedded inorganic clays of medium plasticity and sand-clay mixtures. The topsoil, referred to here as growth media, consists of fine grained sand, sand-clay mixtures, and medium plasticity clay. The agronomic descriptions of these soils are given in the CCP Section 4.4. The soil that is intended to be used for the growth media that will cover the radon barrier of the waste pile and disposal cell is classified as silty sand (SM), sand-clay mixtures (SC), and low to medium plasticity clay (CL) per the Unified Soil Classification System (USCS) and as sandy loam and clay loam per the USDA classification system (HEAL, 2014). It occurs as a residual soil derived from weathering of Mesa Verde sedimentary rock or colluvial/ alluvial soil from erosion of up-slope rock outcrops, including basalt. Based on Table 1 of the Closeout Plan

Guidelines for Existing Mines (MARB 1996) that are part of the State of New Mexico Energy, Minerals and Natural Resources Department (EMNRD) of Mining Act Reclamation Program (MARP) Attachment #1, Soil and Topsoil Suitability Ratings, this soil is rated as good to fair for texture.

During mine construction, site soils were excavated to create pond basins and other surficial features on the site. Most of the excavated soil was used to construct pond berms and to adjust grades for mine surface facilities. Local soils will be used for the growth media and will be obtained primarily from existing borrow areas, by excavations on site or borrow areas adjacent to the mine site, and regrading of pond berms or other grading performed during ground preparation. Table 4.3 (CCP) lists the available soil volumes versus borrow soil required for closeout; ample soil is available from these various sources, all within the mine permit boundaries.

### 2.2.1 Growth Media for Waste Rock Pile and Disposal Cell Cover

According to the latest design, a 33-inch layer of growth media (comprised of a piedmont soil) will be placed on top of the radon barrier, then a 12-inch rock mulch layer for erosion protection will be placed on the top surface of the cell cover. The rock mulch will be approximately 30% 2-inch minus and 70% pediment soils by volume. During placement, only light compaction of the piedmont soil will occur as a result of equipment movement used to place, spread, and grade the loam soil. Soil textures for the growth medium will follow the USDA classification system.

Growth media will be placed on the disposal cell by truck and spread primarily by dozer or motor-grader. The appropriate soil thickness will be achieved by GPS-guided equipment following the soil cover grading plan. The thickness of the placed loam cover is verified by sampling of soil depth using hand-augured holes through the completed growth medium. Thickness verification measurements will be made at least every ¼ acre. RGR will utilize an independent QA/QC contractor to obtain these measurements and validate the growth media layer thicknesses. For each location, the measurements will be documented and reviewed to ensure that the minimum thickness of growth media is attained. Where growth media layer thicknesses are insufficient, additional material will be placed to correct the deficiencies.

#### *2.2.1.1 Biointrusion*

Biointrusion can occur from plants, mammals, and insects. In general, upland plants in the region, even potentially deep-rooted shrubs, have the majority of their roots in the top 25 cm of the soil profile because the plants are primarily relying on precipitation to maintain. At the Homestake – Grant Reclamation Project, Cedar Creek observed a saltbush taproot growing laterally at approximately 20 cm depth. This is evidence that the plant rooting will develop where plant available water is. In the context

of the cover, the plant roots would not be expected to penetrate the radon barrier because plant available water would not be found in the radon barrier. If precipitation were to percolate deep into the soil profile, it would be expected to rest on top of the radon barrier. Due to the compaction, the plants would respond by forming fine dense roots in the vicinity to use the available water. Therefore, plant biointrusion is generally not a concern on the cover.

In general, it is likely that small mammals will inhabit the cover over time. High concentration of burrows and tunnels affect soil morphology and are likely to increase percolation rates. However, the majority of species with the potential to inhabit the area have shallow burrowing depths that leave them unlikely to interact with the radon barrier. Prairie dogs and badgers pose the highest risk to the cover as they may burrow deep enough to affect the radon barrier and form many wide burrows.

There are many species of insects that may be present on the cover. In general, the species of flies, wasps, crickets, and beetles, that have subterranean habits are unlikely to burrow more than a maximum of 12 inches into the ground and generally only burrow down to 6 inches. However, ants and termites, which can burrow upwards of 6 and 30 feet underground, respectively, are possible risks to the cover.

Overall, the cover design of using a rock mulch layer, with 30% 2-inch minus rock by volume, on the top surface generally discourages burrowing from insects and small mammals but the care and maintenance plan for the cover should include observations of small mammal burrows and insect mounds to ensure the effectiveness of the cover.

### 2.2.2 Growth Media for Contaminated Soil Clean-up Areas

When the excavation of contaminated soil has been finished, RGR will determine whether at least six inches of clean soil remains in place in areas to be revegetated. An agronomic assessment will be implemented to determine whether the remaining soils exhibit suitable physical, chemical, and fertility parameters to establish and sustain plant growth. Organic amendments or supplemental growth media may be used to address agronomic deficiencies.

## 2.3 Seedbed Preparation

Native arid vegetation is ecologically adapted to low fertility systems. Therefore, using standard agronomic fertility ranges designed for intensively managed, often heavily irrigated, and annually harvested agricultural systems is misrepresentative of the requirements for arid grassland and shrub systems in New Mexico.

When soil materials are disturbed (plowed, harvested, tilled), organic matter and associated fertility can be released (volatilized) by a subsequent increase in microbial activity. Incorporation of compost to

improve germination conditions for the revegetation surface is recommended. Soil organic matter serves as a reservoir of nutrients for vegetation, provides soil aggregation (providing structure), increases nutrient exchange, retains moisture, reduces compaction, reduces surface crusting, and increases water infiltration into soil. Organic matter increases the water holding capacity as it alters particle aggregation and pore size distribution. Water holding capacity of soil materials is an important consideration for land reclamation. Suitable soil water content is essential for seed germination, seedling establishment, and plant survival as desiccation is a major risk on disturbed sites, especially in arid environments.

Compost is a mixture of organic residues (manure or biosolids or green waste, straw, etc.) that have been piled, mixed and moistened to undergo thermophilic decomposition. Enough compost amendment should be incorporated into the project soils to add 1% organic matter to the top 3 inches of soil. Therefore, a general application rate of 8 cubic yards per acre incorporated to 3 inches depth of composted cow or green manure, or composted biosolids, should be sufficient for reclamation on the tailings site. Suitable material will have at least 25% organic matter, pH not to exceed 8.5, soluble salts less than 10 mmhos/cm, and carbon to nitrogen ratio between 10:1 and 20:1. Moisture content, salinity, and organic matter, of organic amendments need to be tested for by a certified laboratory. All testing should be conducted on representative samples of material from the same batch intended to be purchased. Given the potential for elevated salts in the soils, only low salt amendments should be used. Composted biosolids will be tested to ensure sufficiently low radium activity concentrations prior to use. In specific instances, such as harvesting growth media from very deep in the soil profile or using material stockpiled for more than a year, increased quantities of manure may be beneficial, and will be addressed on an "as needed" basis.

Composted manures and composted biosolids are more desirable than inorganic fertilizers and industrial byproducts such as Biosol, because they are significantly lower in inorganic and total nitrogen. Nitrogen preferentially stimulates the growth of undesirable weedy annual species, which reduces available water and nutrients for desirable perennial vegetation. In addition to the low nitrogen levels, the physical structure of the compost increases localized water holding capacity and creates "islands" of fertility to aid germination. Plant germination and establishment in the first few years is critical, as native seed sources then begin to supplement the initial seeding and stabilize the soil medium. Organic amendment application should occur immediately prior to seeding, and be incorporated as soon as

possible, preferably by disk harrow. Composted manure and/or biosolids left on the soil surface, exposed to warm temperatures and potential precipitation, will readily decompose, thus making it less beneficial.

## 2.4 Seeding

The proposed seed mix is comprised of all native species and application rates are presented on the table below and is optimized for site edaphic and climatic conditions. Each included species was evaluated for the following factors:

- Species Range
- Adapted to Project Soils
- Performance on Local Revegetation
- Species Dominance in Local Ecological Communities
- Precipitation Zones

These factors were also considered when recommending application rate, which was determined by seeds per square foot. Seeding can be accomplished using either broadcasting and drilling techniques (as recommended on the seed mix), following final contouring and compost application/incorporation. Seeding season shall be March 1 to April 30 or October 1 to November 30. In certain circumstances, seeding prior to the monsoonal period (in June or July) may be appropriate as well. Efforts will be made to implement seeding at optimal times for site conditions (late fall/early spring). However, if a unit must be seeded during inopportune months, a field level risk assessment will determine whether temporary erosion control measures (such as crimped hay, wood shreds, wattles, etc.) are needed to stabilize the surface prior to anticipated vegetation establishment. Drill seeding techniques cannot be used on extremely rough surfaces and in areas with slopes of 3H:1V or steeper (natural or cut slopes east of the shafts). In these situations, seed will be broadcast, and a light disc harrowing perpendicular to the flow of energy (wind and/or water) should immediately follow seeding to increase seed to soil contact and provide some protection from wind or water erosion and granivory. Hydroseeding may also be used in a

two-pass system, where the first pass is dedicated to sowing most of the seed and the second pass installs the mulch. The disposal cell will be seeded with this mix.

## 2.5 Erosion Control

The principle means to obtain erosional stability on the disposal cell is rock armor. Vegetation establishment and persistence will serve as the primary erosion control measure for other revegetation. A field level risk assessment will determine whether temporary erosion control measures (such as certified weed-free crimped hay, wood shreds, wattles, etc.) are needed to stabilize the surface prior to anticipated vegetation establishment.

## 2.6 Climate Change Considerations

Climate change modeling results provide general indications of how the climate may shift in New Mexico over the next several decades and into the next century, albeit with a significant degree of uncertainty, spatially, temporally, and degree of magnitude. In general, modeling results from the Nature Conservancy and the Southwest Climate Change Network indicate a general warming and drying trend (with localized instances of cooling and increases in precipitation), with increased variation in timing, intensity, and form of precipitation from typical averages. The species selected for revegetation are well suited to the current arid climate of this region, yet have a relatively wide tolerance to climatic conditions, particularly regarding the predicted result of climate change (warmer and drier). In other words, if precipitation decreases, drought increases, or temperatures and subsequent evaporation rates rise, these species will still be suitable for and tolerant of future climates projected in the region. The anticipated circumstances of climate change may actually select for more efficient, later seral species (as is a desired outcome for the project), over short-lived annuals and less efficient cool season grasses.

## 3.0 VEGETATION SAMPLING METHODS

Revegetation monitoring will consist of both qualitative and quantitative protocols. Qualitative protocols record any deficiencies in vegetation, both general and localized, and any other pertinent information relative to the reclamation is also recorded while traversing monitoring units during vegetation evaluations. During these traverses, the observer is vigilant for: 1) areas of poor establishment/growth, 2) pervasively weak or stressed plants, 3) indicators of soil fertility problems (e.g., certain anthocyanine colorations), 4) noxious weeds or invasive plant infestation, 5) evidence of unintended livestock grazing, 6) excessive erosion, 7) "pockets" of the aforementioned, and 8) any other similar revegetation / reclamation related issues. Quantitative protocols are described in the following sections.

Reference areas should be used as a benchmark for revegetation success. Appropriate reference areas will be selected in coordination with the New Mexico Mining and Minerals Division (MMD) prior to implementing revegetation monitoring and should provide a suitable target for revegetation performance by representing project topographic and edaphic conditions.

### 3.1 Sample Site Selection / Location

The systematic procedure for the determination of sample locations occurs in the following stepwise manner. First, a fixed point of reference is selected for the entire area to facilitate location of the systematic grid in the field. Second, a systematic grid of appropriate dimensions (i.e., 200 ft X 200 ft) is selected to provide a minimum number of coordinate intersections; reclaimed areas are conducted to a minimum of 20 transects whereas reference area sampling is conducted to a minimum of 15 initial transects. Third, a scaled representation of the grid is overlain on field maps extending parallel to major compass points to facilitate field location. Fourth, unbiased placement of this grid is controlled by selection of a random origin. Fifth, utilizing a GPS, all of the initial sample points are located in the field.

### 3.2 Determination of Ground Cover

Ground cover at each sampling site is determined utilizing the point-intercept method (Bonham 1989) as illustrated on Figure 1. Implementation of the technique for the sampling effort occurs as follows: First, a transect of 10 meters length is extended from the starting point of each sample site toward the direction of the next site to be sampled. Then, at each one-meter interval along the transect, a "laser point bar" is situated vertically above the ground surface, and a set of 10 readings recorded as to foliar hits on vegetation (by species), litter, standing dead, rock (>2mm), or bare soil. Hits are determined at each meter interval by activating a battery of 10 specialized lasers situated along the bar at 10-centimeter intervals and recording the variable intercepted by each of the narrow (0.02 inch)

focused beams (see Figure 1). In this manner, a total of 100 intercepts per transect are recorded resulting in 1 percent foliar cover per intercept.

### 3.3 Determination of Woody Plant Density

At each sample site, a 2-meter-wide by 50-meter-long belt transect is established parallel to the ground cover transect and in the direction of the next sampling point (in a cardinal compass direction – Figure 1). Occasionally 4 x 25 meter transects are employed where distance between points necessitates shorter belts. Then within each belt, all woody plants (shrubs, trees, and succulents) are enumerated by species and age class. Determination of whether or not a plant could be counted depends on the location of its main stem or root collar where it exited the ground surface with regard to belt limits.

### 3.4 Determination of Productivity

At each sample site, current annual production is collected from a 1/2 $m^2$ quadrat frame at each sampling location. Utilization and development will be estimated using on the ground observations of herbivory within each of these quadrat frames. The quadrat is placed one meter and 90º to the right (clockwise) of the ground cover transect to avoid vegetation trampled by investigators during sample site location. From within each quadrat, all above ground current annual vegetation within the vertical boundaries of the frame is clipped and bagged separately by life form as follows:

| | |
|---|---|
| Native Perennial Cool Season Grass | Shrub |
| Native Perennial Warm Season Grass | Sub-Shrub |
| Introduced Perennial Grass | Native Perennial Forb |
| Annual Grass | Introduced Perennial Forb |
| Noxious Weed | Native/Introduced Annual/Biennial Forb |

All production samples are returned to the lab for drying and weighing. Drying will occur at 105º C until a stable weight is achieved (typically 24 hours). Samples will then be weighed to the nearest 0.1 gram. Utilization and growth stage adjustments will be incorporated into the presentation of results.

### 3.5 Determination of Emergent Density

In the first growing season following seeding, between 5-15 samples are collected from each reclaimed unit. Each sample consists of a cluster of five 1.0 $ft^2$ quadrats distributed in an unbiased manner. Following a random toss of each quadrat, the number of emergent plants rooted within the frame's perimeter is recorded accordingly into one of five classes: perennial grass, perennial forb, shrub/tree (by species), annual grass, or annual forb.

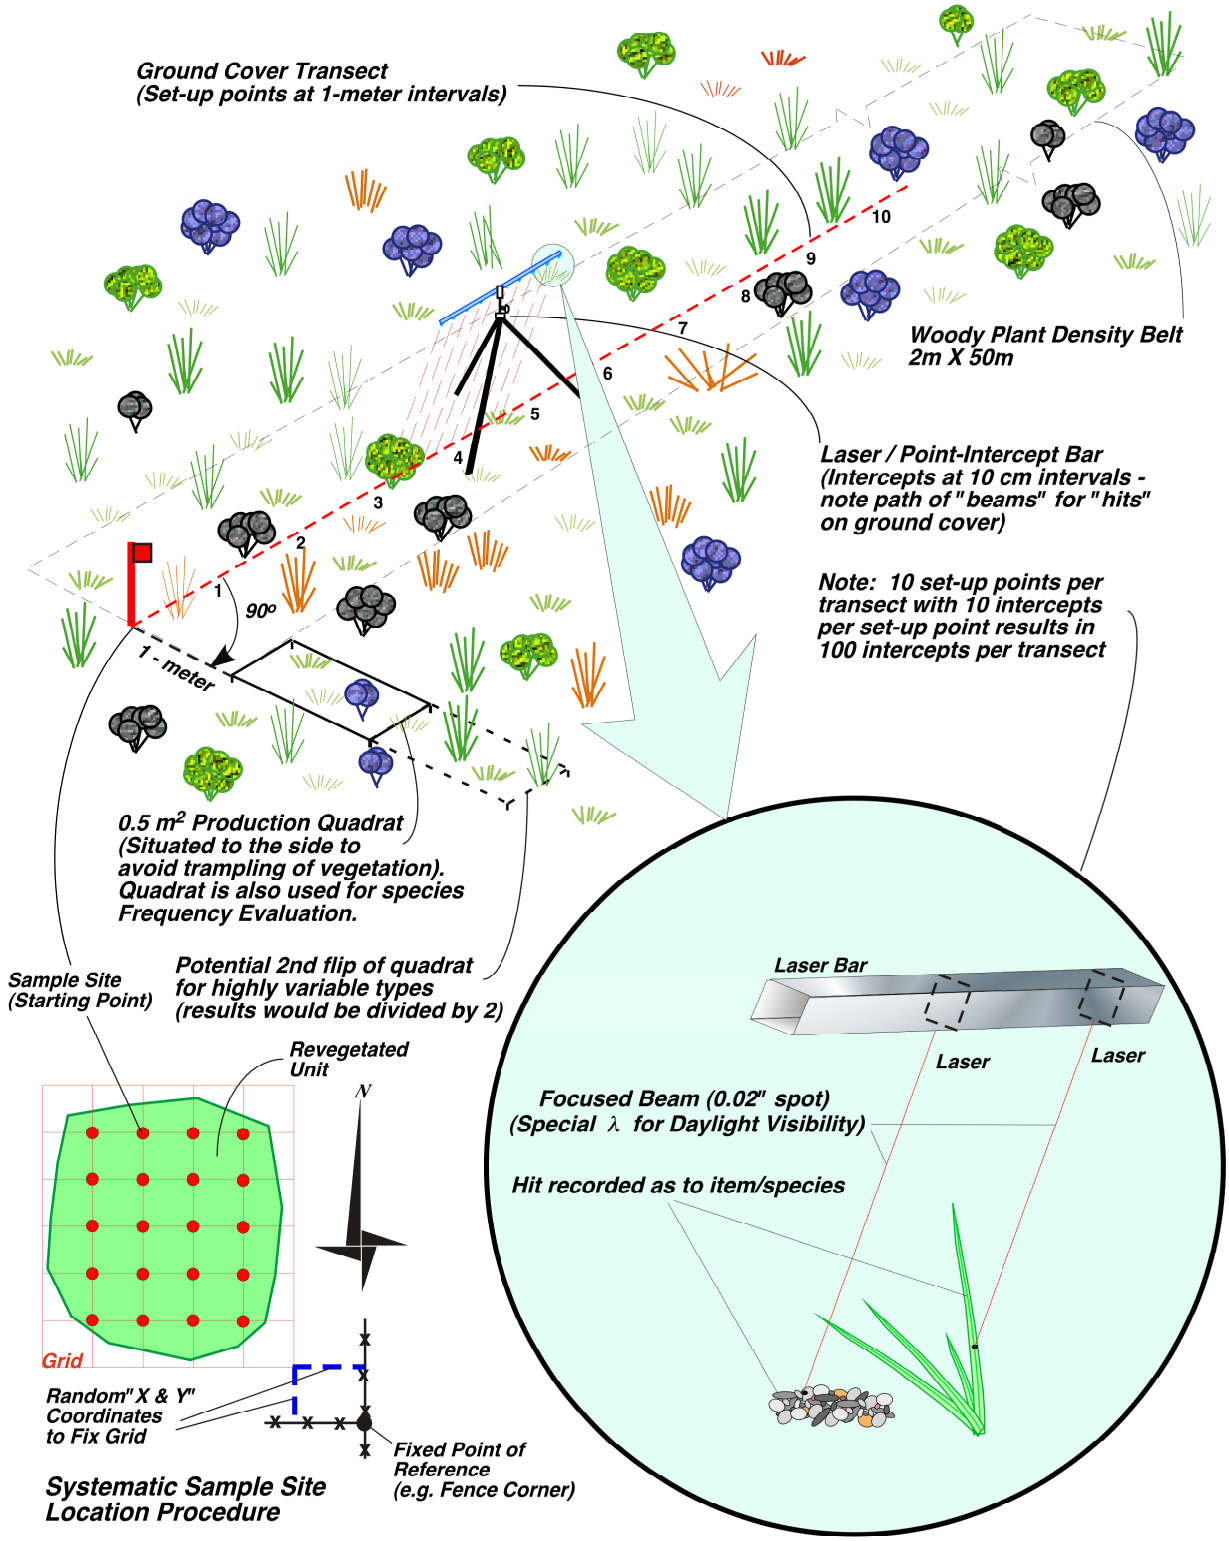

***Figure 1***

***Sampling Procedure at a Systematic Sample Site Location***

**Figure 1: Sampling Procedure**

## 4.0 REVEGETATION MONITORING SCHEDULE AND SUCCESS EVALUATIONS

### 4.1 Monitoring Schedule

The revegetation liability period (period of time that the owner is responsible for revegetation performance) under the MMD framework is 12 years with monitoring every three years. The annual site visits for the revegetation will be as follows:

Year 1 – Emergent Density Evaluation
Year 3 – Qualitative and quantitative evaluations (managerial information only).
Year 6 – Qualitative and quantitative evaluations (managerial information only).
Year 9 – Qualitative and quantitative evaluations (managerial information only).
---
Year 11 – Qualitative and quantitative evaluations (final success evaluation).
Year 12 – Qualitative and quantitative evaluations (final success evaluation).

As indicated, the final efforts, during year 11 and 12, would be an evaluation for success determination. Years 11 and 12 evaluations will be conducted in such a manner as to provide defensible verification that success has been achieved. If it is determined that vegetation needs additional time to mature, monitoring will continue once every 3 years, thereafter, until success evaluations are positive. Other than first year efforts, annual monitoring would be a combination of both qualitative and quantitative efforts to facilitate tracking and progress toward revegetation success standards.

### 4.2 Success Criteria

The primary post mining land use is anticipated to be grazing, therefore, revegetation success in revegetated units will concentrate on four performance standards (1) vegetative ground cover, and 2) diversity, 3) woody plant density, and 4) productivity. Revegetation efforts will be considered successful when the following criteria have been met. The reference areas will be sampled along with the revegetation to provide a suitable comparison each year of assessment. In this manner, the success criteria is dynamic and adjusts to climatic conditions.

1. Vegetative Ground Cover Standard

   The target revegetated unit equals or exceeds 70% of an appropriate reference area absolute desirable vegetative ground cover (exclusive of listed noxious species), with 90 percent statistical confidence. Desirable vegetation excludes noxious and nuisance (non-

native annual weeds) but includes other annuals and perennials which are native and non-native.

2. Species Diversity Standard:

   Ground cover shall be comprised of a minimum of three perennial grass species, one perennial forb species, and one shrub species to address species diversity.

3. Woody Plant Density Standard:

   Woody Plant Density, as indicated by number of stems per acre in the revegetated unit equals or exceeds 200 stems per acre.

4. Productivity Standard:

   The target revegetated unit equals or exceeds 70% of an appropriate reference area absolute desirable vegetative productivity (exclusive of listed noxious species and succulents). Desirable vegetation excludes noxious and nuisance (non-native annual weeds) but includes other annuals and perennials which are native and non-native.

## 4.3 Sample Adequacy Determination

Ground cover sampling within reclaimed areas is conducted to a minimum of 20 initial transects whereas reference area sampling is conducted to a minimum of 15 initial transects. From these preliminary efforts, sample means and standard deviations for total non-overlapping vegetation ground cover are calculated. The procedure is such that sampling continues until an adequate sample, $\mathbf{n_{min}}$, has been collected in accordance with the Cochran formula (below) for determining sample adequacy, whereby the population is estimated to be within 10% of the true mean (μ) with 90% confidence. These limits facilitate a very strong estimate of the target population (MMD 1996).

When the inequality ($\mathbf{n_{min}} \leq \mathbf{n}$) is true, sampling is adequate and $\mathbf{n_{min}}$ is determined as follows:

$$\mathbf{n_{min} = (t^2 s^2) / (0.1\ \bar{x}\ )^2}$$

where: n = the number of actual samples collected

$t$ = the value from the one-tailed $t$ distribution for 90% confidence with n-1 degrees of freedom

$s^2$ = the variance of the estimate as calculated from the initial samples

$\bar{x}$ = the mean of the estimate as calculated from the initial samples

If sampling is designed for a formal success evaluation and the initial samples do not provide a suitable estimate of the mean (i.e., had the inequality been false), additional samples will be collected until the inequality ($\mathbf{n_{min}} \leq \mathbf{n}$) becomes true or until a maximum of 40 samples are collected. If sample adequacy is not achieved after 40 samples are collected, a reverse null approach will be used to demonstrate success. The demonstration of success will utilize the central limit theorem which assumes approximate normality when a sufficiently large number of samples are collected (greater than 30). A one-sided, one-sample, reverse–null t-test is considered appropriate. Since sampling adequacy is not required (nor recommended) for woody plant density, one density belt will be co-located with each ground cover transect, but adequacy shall not be tested for this variable. Resulting data can then be considered reasonable for the evaluation purposes intended.

## 5.0 MANAGEMENT ACTIONS / CONTINGENCY

After the initial seeding occurs and monitoring has begun, circumstances may require additional management actions to facilitate revegetation parcels toward the desired outcomes. The management actions presented below may not represent an exhaustive list of potential options, as additional management alternatives may be needed to address site-specific issues that arise.

### 5.1 Inter-seeding

If undesirable precipitation, wind events, or any other factors contribute to poor seed germination, additional seed may be broadcast or drilled (if topography allows) to increase vegetative cover or diversity, as required.

### 5.2 Weed Control

Weed management may be implemented if noxious weeds identified during annual vegetation surveys present an obstacle to achieving performance criteria for the cover. Noxious weed control is species-dependent and both method and timing will vary from species to species. Should the need arise, noxious weed patches will be identified and delineated with a GPS during the annual vegetation survey. Data regarding the species and density of the population will be recorded, and then an informal control plan will be formulated and implemented. The effectiveness of control methods will be documented during the following annual vegetation survey.

Prevention is the highest priority weed management practice on non-infested lands; therefore, protecting weed-free plant communities is the most economical and efficient land management practice. Prevention is best accomplished by ensuring that new weed species seed or vegetative reproductive plant parts of weeds are not introduced into new areas and early detection of any new weed species before they begin to spread. Control methods may include chemical or mechanical approaches. The optimum method for weed management varies depending on a number of site-specific variables such as associated vegetation, weed type, stage of growth, and severity of the weed infestation.

#### 5.2.1 Chemical Control

Chemical control consists of selective and non-selective herbicides. Target noxious weed, herbicide selection, proximity to desirable plant species, and timing are considerations for chemical control. The use of herbicides would be in compliance with all Federal and State laws on proper use, storage, and

disposal. The chemical application would be done by a licensed contractor in accordance with all applicable laws and regulations and all label instructions will be strictly followed.

### 5.2.2 Mechanical Control

Mechanical control is the physical removal of weeds and includes tilling, mowing, and pulling undesirable plant species. Treatment options and efficacy depend on the noxious weed targeted and method used.

## 5.3 Mulching

If revegetation parcels are eroding at an unforeseen rate while vegetation is still being established, mulch may be used to provide rainsplash and wind protection, reduce evaporation, and stabilize the seedbed. Preferably, a wood fiber or wood shred mulch would be used, as it is more robust than hay or straw and more likely to provide wind protection.

If used, wood fiber mulch or wood shred mulch would consist of specially prepared wood fibers and would not be produced from recycled material such as sawdust, paper, cardboard, or residue from pulp and paper plants. If necessary, such as on a steep slope or an area deemed a high wind erosion risk area, a tackifier can be used with the wood-fiber mulch to improve adhesion. If erosion areas are localized, small, or well sheltered, a simple straw mulch should suffice in providing rainsplash protection. Interseeding would most likely be necessary if erosion is sufficient enough to require post-revegetation corrective mulching.

## 5.4 Supplemental Irrigation

The seed mix proposed for this project is comprised of species adapted to the local climactic conditions and supplemental irrigation is not likely required to establish vegetation. Irrigation typically causes an artificial climactic regime that overly encourages annual weeds versus the desired seeded species. Also, under the influence of irrigation, the adapted plants that do germinate will develop above ground biomass at the expense of below ground biomass. Once the irrigation stops, those plants have essentially become "accustomed" to artificial circumstances and will typically die during a normally tolerated drought. Over approximately the last 20 years, practical applications of arid land reclamation science have abandoned the use of irrigation.

However, a prolonged drought during the plant establishment period could become detrimental to the project. In this specific circumstance, supplemental irrigation may be used to facilitate germination, but procedures for implementing irrigation need to be highly managed and not exceed 120% of any

monthly precipitation average. Soil moisture sensors and unsaturated flow modeling should accompany the planning and implementation of irrigation events to facilitate vegetation establishment and growth, while maintaining the primary function of isolating the buried materials from the water balance. Per the New Mexico Mining and Minerals Division comments on the CCP (May 10, 2023), irrigation of revegetated areas will only be permitted for the first three years after seeding.

To encourage and sustain perennial growth, particularly of warm season grasses and shrubs, and discourage annual weedy species, irrigation needs to occur as infrequent pulses of relatively substantial quantities of water, in an attempt to mimic the natural monsoonal precipitation experienced in mid to late summer. These irrigation events, mimicking high intensity, short duration convective thunderstorms will increase the amount of plant available water, facilitating the robust and extensive root systems needed for survival of perennial vegetation beyond irrigation. In contrast, frequent and shallow irrigation events will benefit the shallow rooted annual species and facilitate perennial root growth near the surface, which during periods of drought will desiccate, and result in the senescence of all shallow rooted vegetation.

## Water Sampling and Laboratory Test Data

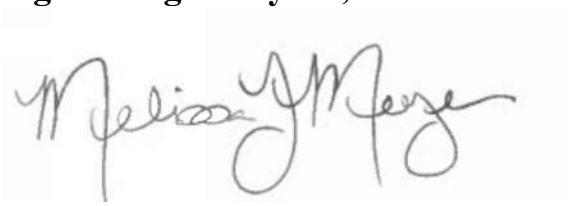
Water Quality Results for the October 2023 Dewatering Well Sampling Investigation

- Tabulated Water Quality Data
- October 2023 Water Quality Sampling Data for Dewatering Wells

June 4, 2025 Project No. 111360

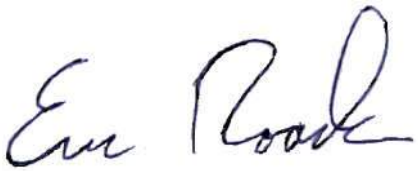
Mr. Corey Dimond
New Mexico Environment Department
Ground Water Quality Bureau
Mining Environmental Compliance Section
1190 St. Francis Dr.
Sante Fe, NM 87502

RE: Rio Grande Resources' Submittal of Pre Rehabilitation October 2023 Dewatering Well Sampling Data from April 28, 2023 Dewatering Well DW-10 and DW-11 Investigation Work Plan prepared by Gard Water



Dear Mr. Dimond,

Included in this document are the water quality results for the October 2023 ewatering well sampling investigation that is the first phase (pre well rehabilitation) of the sampling requested in the February 23, 2023 NMED Request for Additional Information on the 15-day Suspected Petroleum Release Report for Dewatering Wells Dw-10 and DW-11, Mt Taylor Mine, San Mateo, New Mexico and outlined in the April 28, 2023 Dewatering Well DW-10 and DW-11 Investigation Work Plan prepared by Gard Water.



Below is a list of tables and attachments included in this letter.

- Tabulated Water Quality Data
  - Tables 1 through 11 contain water quality data for DW-1, DW-2A, DW-2, DW-3, DW-6, DW-7, DW-8, DW-9, DW-10, DW-11, and DW-12 respectively.
- Attachment A October 2023 Water Quality Sampling Data for Dewatering Wells Includes the following reports
  - October 4, 2023 L1662801 Pace Analytical Report on DW-1 and DW-7
  - October 7, 2023 L1664135 Pace Analytical Report on DW-10 and DW-12
  - October 7, 2023 L1664199 Pace Analytical Report on DW-2 and DW-9
  - October 13, 2023 L1666511 Pace Analytical Report on DW-3 and DW-11
  - October 13, 2023 L1666516 Pace Analytical Report on DW3, DW-2a, and DW-6
  - October 13, 2023 L1666531 Pace Analytical Report on DW-8 and DW-10

Respectfully Submitted,
**Engineering Analytics, Inc.**

Acronyms: Reporting Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH), Point Discharge (PD)

Dark grey shading in cells idicates a concentration was measured above RDL

Yellow shading in cells indicates a concentration was measured above NMWQCC-3102 Standards

Blue indicates a concentration was measured above RDL in a blank sample

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

2: Sample was collected from spigot near well head

3:The targeted sample depth was unable to be met due to unforeseen obstruction. The depths listed for the sample ID for the blanks is the targeted sample depth and the depth listed for the representative sample is the deapth reached in the field.

Acronyms: Reporting Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH), Point Discharge (PD)

Dark grey shading in cells idicates a concentration was measured above RDL

Yellow shading in cells indicates a concentration was measured above NMWQCC-3102 Standards

Blue indicates a concentration was measured above RDL in a blank sample

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

2: Sample was collected from spigot near well head

3:The targeted sample depth was unable to be met due to unforeseen obstruction. The depths listed for the sample ID for the blanks is the targeted sample depth and the depth listed for the representative sample is the deapth reached in the field.

Acronyms: Reporting Limit (RDL), Feet Below Top of Casing (fbtoc), Quality Control (QC) Total Petroleum Hydrocarbons (TPH), Point Discharge (PD)

Dark grey shading in cells idicates a concentration was measured above RDL

Yellow shading in cells indicates a concentration was measured above NMWQCC-3102 Standards

Blue indicates a concentration was measured above RDL in a blank sample

Footnotes:

1: The "less than" symbol "<" is a method to convey that the target analyte was not encountered above the RDL.

2: Sample was collected from spigot near well head

3:The targeted sample depth was unable to be met due to unforeseen obstruction. The depths listed for the sample ID for the blanks is the targeted sample depth and the depth listed for the representative sample is the deapth reached in the field.

# CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

John Hawkins
Project Manager

## Volatile Organic Compounds (GC) by Method 8015D/GRO

| Analyte | Result mg/l | Qualifier | RDL mg/l | Dilution | Analysis date / time | Batch |

# GLOSSARY OF TERMS

## Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

## Abbreviations and Definitions

| | |
|---|---|
| MDL | Method Detection Limit. |
| ND | Not detected at the Reporting Limit (or MDL where applicable). |
| RDL | Reported Detection Limit. |
| Rec. | Recovery. |
| RPD | Relative Percent Difference. |
| SDG | Sample Delivery Group. |
| (S) | Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media. |
| U | Not detected at the Reporting Limit (or MDL where applicable). |
| Analyte | The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported. |
| Dilution | If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor. |
| Limits | These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges. |
| Original Sample | The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG. |
| Qualifier | This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable. |
| Result | The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte. |
| Uncertainty (Radiochemistry) | Confidence level of 2 sigma. |
| Case Narrative (Cn) | A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report. |
| Quality Control Summary (Qc) | This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material. |
| Sample Chain of Custody (Sc) | This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis. |
| Sample Results (Sr) | This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported. |
| Sample Summary (Ss) | This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis. |

| Qualifier | Description |
|---|---|
| J4 | The associated batch QC was outside the established quality control range for accuracy. |

# CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

John Hawkins
Project Manager

## Volatile Organic Compounds (GC) by Method 8015D/GRO

| Analyte | Result mg/l | Qualifier | RDL mg/l | Dilution | Analysis date / time | Batch |

# GLOSSARY OF TERMS

## Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

## Abbreviations and Definitions

| | |
|---|---|
| MDL | Method Detection Limit. |
| ND | Not detected at the Reporting Limit (or MDL where applicable). |
| RDL | Reported Detection Limit. |
| Rec. | Recovery. |
| RPD | Relative Percent Difference. |
| SDG | Sample Delivery Group. |
| (S) | Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media. |
| U | Not detected at the Reporting Limit (or MDL where applicable). |
| Analyte | The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported. |
| Dilution | If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor. |
| Limits | These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges. |
| Original Sample | The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG. |
| Qualifier | This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable. |
| Result | The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte. |
| Uncertainty (Radiochemistry) | Confidence level of 2 sigma. |
| Case Narrative (Cn) | A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report. |
| Quality Control Summary (Qc) | This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material. |
| Sample Chain of Custody (Sc) | This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis. |
| Sample Results (Sr) | This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported. |
| Sample Summary (Ss) | This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis. |

## Qualifier Description

| Qualifier | Description |
|---|---|
| B | The same analyte is found in the associated blank. |
| J | The identification of the analyte is acceptable; the reported value is an estimate. |
| J3 | The associated batch QC was outside the established quality control range for precision. |
| J4 | The associated batch QC was outside the established quality control range for accuracy. |
| J5 | The sample matrix interfered with the ability to make any accurate determination; spike value is high. |

# CASE NARRATIVE

All sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times, unless qualified or notated within the report. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

John Hawkins
Project Manager

## Volatile Organic Compounds (GC) by Method 8015D/GRO
